# Organizational issues

## Structure of the unit

COMP11120 is a 20 credit course unit that is taught over two semesters. You will receive one mark at the end of the unit, and it is that mark which decides whether you pass or fail.

For internal purposes the first semester sometimes appears under the course code COMP11121, and the second as COMP11122, for example in Arcade.

The webpage for this course is at

[www.studentnet.cs.manchester.ac.uk/ugt/COMP11120](http://www.studentnet.cs.manchester.ac.uk/ugt/COMP11120).

Electronic copies of these notes are available there. This unit does have a presence in Blackboard<sup>1</sup>, and some material will be published there. Note that the electronic version of the notes shows colours, while the printed version is black and white, and that it has clickable links that allow you to follow references within the text easily.

## When and where

The unit is taught with two lectures and one examples class per week.

### Semester 1

Please refer to your personal timetable regarding the time and location of lectures.

For the examples classes you are split into four lab groups. Which group you are in is determined by the letter part of the name of your tutorial groups. Examples classes take place as follows:

- **Group W:** Fridays 14.00 in G102;
- **Group X:** Fridays 13.00 in G102;
- **Group Y:** Tuesdays 15.00 in G102.
- **Group Z:** Tuesdays 14.00 in G102;

Examples classes start in Week 1 and run through to Week 12.

---

<sup>1</sup>This is the University's E-learning environment.

## Semester 2

Lectures take place<sup>2</sup>

- Wednesdays 9.00 in 1.1 and
- Thursdays at 10.00 in 1.1.

Examples classes take place

- **Group W:** Thursdays 15.00 in G102;
- **Group B+X:** Tuesdays at 14.00 in G102;
- **Group Y:** Thursdays at 14.00 in G102;
- **Group Z:** Tuesdays at 15.00 in G102.

## Who

This course unit is taught by two members of staff:

- Renate Schmidt [Renate.Schmidt@manchester.ac.uk](mailto:Renate.Schmidt@manchester.ac.uk),
- Andrea Schalk, [A.Schalk@manchester.ac.uk](mailto:A.Schalk@manchester.ac.uk) (course leader).

## Assessment

### Overview

The assessment of this course unit has the following components:

75% Two 2 hour end of term examinations, one after Semester 1 and one after Semester 2, with

- the Semester 1 exam making up<sup>3</sup> 35% and
- the Semester 2 exam making up 40% of the final mark.

25% Coursework. This is split further into

5% Midterm test on 14th November at 12.00 in Theatre 1 in Crawford House in Semester 1.

10% Assessed exercises for Semester 1. These are checked in the examples classes each week.

10% Assessed exercises for Semester 2. These are checked in the examples classes each week.

---

<sup>2</sup>There may be changes to the timetable for Semester 2.

<sup>3</sup>Combined with the mid-term test that adds up to 40%, which means that Semester 1 counts the same as Semester 2.

## Examinations

There are written examinations after both, Semester 1 and Semester 2. Note that this course unit has been substantially revised in recent years and reached its current format in 2015/16. As a consequence exam papers before that year do not accurately reflect the kind of paper you will sit. The exams are based mostly on questions which are similar to the core questions from the examples classes, with a few marks (at most 20%) available for questions beyond that.

There are three questions in each paper, one each for the major topics covered in that semester. This means that in **Semester 1** there will be one question each on

- statements and proofs;
- logic;
- probability,

while in **Semester 2** there will be one question each on

- recursion and induction;
- relations;
- linear algebra.

Either exam may contain some material covered in the relevant semester in the shorter chapters on complex numbers, comparing sets and functions and examples from computer science. If something has appeared in an examples class it may be in the exam for that semester. Note that examples that were taught in Semester 1 may appear in the paper for Semester 2 (so a question on relations could involve, say, complex numbers).

## Mid-term test

There is a test around the middle of Semester 1. It prepares you for the examination in January and gives you an idea how well you have understood the material taught so far. The questions will be similar to the exercises in the notes, and two previous tests with solutions are available from the course webpage.

## Assessed exercises

Note that in the first examples class in Week 1 we will not give marks. We expect you to try to solve the exercises from Chapter 0 given on the relevant sheet.

For each examples classes you are told to prepare a number of exercises (typically five exercises per week, see the sheets at the end of the notes). In some cases you have a choice regarding which exercises you want to do. This is to ensure that students who have seen similar material before still have something interesting to do. The exercises typically are about looking at a particular concept or technique. All the parts of some exercise are concerned with the same abstract property, so no matter which ones you do you will familiarize yourself with that property.

There are two kinds of exercises:

- **Core.** These belong to the core of the taught material, and there are typically three such exercises each week. They are named as *CExercise* in the notes.
- **Extensional.** These questions extend the core material and they are named as *EExercise* in the notes.

If you are stuck on one exercise for ten minutes without making progress then *move on to the next one*. Also note that the different parts to each exercise are *not necessarily in rising order of difficulty*.

The point of the examples classes are

- to give you feedback on whether you have understood the material and answered the exercises correctly with the right level of detail, and
- to help you with exercises you had difficulties solving, concentrating on the core exercises.

The rules for assessing exercises are quite simple. The **deadline** is the beginning of each examples class. If you are more than five minutes late you have to have a good reason, which you have to explain to the member of staff present. Otherwise your mark will be 0 for the week.

The **deliverables** are:

- A piece of paper with your solution to the exercise.
- More pieces of paper with all your rough work.<sup>4</sup>
- You being able to explain your solution *promptly* when asked.

If you cannot explain your work when the teaching assistant<sup>5</sup> asks you to do so, or if you do not have your rough work with you, you will lose some or all of the marks for the given week.

Each exercise is **marked out of 2**, with the following mark allocation:

- 0 marks: You cannot prove that you made a serious attempt to solve the exercise before the start of your examples class.
- 1 mark: You can demonstrate that you made a serious attempt to solve the exercise before the start of the examples class but you are a some distance away from the correct solution, or you have not given enough detail. At a *minimum* you should
  - copy the relevant definition(s) from the notes (the Glossary near the end will help you find those),
  - identify similar examples in the notes and
  - be able to describe to the TA where you got stuck.

If with a little help from the TA you can complete your answer you may be able to move from 1 to 2 marks for that exercise.

---

<sup>4</sup>Nobody will look at these in detail and there's no need to be embarrassed about what it looks like.

<sup>5</sup>Teaching assistants used to be called demonstrators in the School. You will still find people referring to demonstrators—it's the same thing. We also refer to teaching assistants as TAs.

- 2 marks: As the previous point, but your solution is largely correct.

You can only get the second mark for an **extensional exercise** if you have solved and completely understood all the **core exercises**. The TAs will ask you whether you have done so. If you say you have, but then cannot answer some questions about the core exercises, the TA will concentrate on those, and not look at your extensional exercises at all. Your maximum mark will then be 6 for that week. If you have questions ready for the core exercises the TA will help with those, and also give you marks for preparing extensional exercises if you have done so. Your maximum mark for that week is 8. If you have completely understood the core exercises and also solved all the extensional ones then your maximum mark for that week is 10.

The TAs have about five minutes per student in each examples class. To get the most out of this it is *vital* that you have your work ready, that you have a list of questions based on what you did not understand, and that you can promptly answer questions asked by the TA. If you are not ready when a TA comes to mark you you will go to the end of the queue, and there may then be less time to answer any questions you have.

It is your job to ask questions, and the TA's job is to answer those as far as possible within the examples classes. It is *not* the job of the TAs to work out what your questions should be based on the solution you show them!

These exercises are assessed work. If you copy somebody else's work you are committing a **plagiarism** offence. If you let somebody copy your work you are also committing plagiarism. This will result in a mark of 0 for the week, and if you commit repeated or particularly serious offences you may have to face School or Faculty panels. See below for a detailed description of what you are allowed to share with other students.

A few days after each examples classes you can check the mark you received in Arcade. Sometimes transcription errors occur. If you find that you have no mark, or the wrong mark, for a particular examples class, then please immediately contact the course leader, Andrea Schalk, at

[A.Schalk@manchester.ac.uk](mailto:A.Schalk@manchester.ac.uk)

or talk to the academic in your next examples class.

**Extensions.** In the interest of providing further feedback, solutions are published after the last examples class each week. As a consequence it is *not possible* to give extensions for the work to be prepared for each week.

However, we count the **best eight out of the ten possible marks** you obtain each semester. This is to account for the fact that students may have to miss some examples classes. You can miss up to two examples classes without having a mark of 0 counting. If you have good reasons to miss more than two examples classes you must fill in a [Mitigating Circumstances form](#) and submit it to the student support office.

Also note that you **must attend at least seven out of ten** examples classes for your coursework mark to count.

If you cannot attend your usual examples class in a week, but are free for another (check the information on page 3 to see when and where these take place) then you should attend that examples class. Please make yourself known at the beginning to the member of staff present, or to a teaching assistant. It will then be possible to mark your work in that examples class.

However, **you must** get permission in advance to attend another examples class from one of the two course unit lecturers.

## The discipline of mathematics

Mathematics is a foundational subject for many sciences and engineering disciplines, and this holds true for computer science as well.

### This course unit

In order to master the subject sufficiently to be able to apply it it is not sufficient to treat mathematics as a series of recipes for various calculations.

Instead mathematics formally defines a number of abstract concepts, and then derives their properties (and so justifies calculations of various kinds). As a discipline mathematics is unique in that its theories may be proved or disproved conclusively. It is not necessary to acquire data to study whether the predictions of a theory match observations from experiments—instead one proves statements based on universally accepted derivation rules.

This course unit provides an introduction to those areas of (abstract) mathematics which are of particular importance in computer science. Its aim is to do so rigorously by introducing various concepts formally, and then to show what properties these have. For this purpose it is also necessary to talk about the notion of proof in order to make it clear how valid derivations are formed. Throughout the notes examples from applications within computer science are given wherever possible.

This is the only course unit teaching mathematics in the curriculum for computer science students in Manchester. It therefore has to lay the foundations for everything that is to follow, and in some cases you will not see the material introduced here until the second, or even the third year.

### How to learn the material

Abstract mathematics requires a fairly lengthy learning process. Typically material has to be studied more than once over a longer period to be fully understood. The point of weekly assessed exercises is to encourage students to try their best to understand various abstract concepts and their uses. In the examples classes you get feedback regarding your understanding, and the revision period should provide another opportunity to improve your understanding before the exams.

Mathematics isn't a spectator sport—the only way to learn it is to do it yourself. Watching others carry out calculations or proofs may be instructive at first, but in the end the only way of properly understanding it is to make your own brain work through the problems given.

You should think of this kind of learning as happening on a spiral: Every time you revisit a topic you will find yourself having achieved a higher level of understanding, provided you really try to get your head around it. This kind of material is not suitable for postponing all the work until revision time. It is also very difficult to catch up once you have fallen behind. For this reason doing set work every week is rewarded by giving you marks, determining 20% of the mark for each semester.

**Notes.** You should think of the lecture notes as providing an account of the *examinable material*. The exercises are part of that material—usually not the specifics but the techniques. You are required to *read the notes independently*. Note that we expect students to know all the numbered definitions where a concept is defined in bold face (some have concepts defined in italics), although we don't ask many exam questions which are just about the definitions. An electronic version of the notes is available from the course webpage. Unlike your printed copy this is in colour, and has links for cross-referenced material.

**Exercises.** You will have worked on some of the exercises as part of the assessed work, the others are available for revision purposes. You will receive solutions to most<sup>6</sup> of the exercises in the course of term. There are also *optional exercises* which are not part of the examinable material, and to which no solutions will be handed out.<sup>7</sup> Note that the exercises appear in the text where they are more appropriate. When working on an exercise for assessed work you will almost certainly have to (re-)read the material preceding the exercise.

**Lectures.** The point of the lectures is to help you understand the notes. This is done by explaining the more abstract or complex concepts, and showing you examples. Not everything that is examinable will be mentioned in a lecture—what is written in the notes counts here.

**Examples classes.** The point of the examples classes is to give you feedback on exercises you have tried yourself, and to help you with to help you with concepts or ideas you are finding difficult.

In that way all the contact hours are dedicated to help you learn the material, but ultimately what you put in yourself will be the biggest decider in what you get out.

**Additional help.** If you find you are struggling with the material there are a number of actions you may take. You may want to consult an alternative text in case the explanations as given in the notes don't suit your way of understanding. You should ask lots of questions in the examples class. You should also talk to your friends on the programme, for example the other members of your tutorial group. It may make sense for some of you to form a study group and to tackle the material together. The weekly PASS sessions are an excellent way of getting help from students who are in their second or third year.

## Expected effort

The School expects students to work around 40 hours a week (although some students put in more). This means that for every ten credit course unit you should expect to work roughly seven hours a week (including contact hours).

In COMP11120 you have three contact hours a week, which means you are expected to work **four hours a week** working through the notes and solving the exercises (in particular the assessed ones).

---

<sup>6</sup>At a minimum this will include solutions to all assessed exercises.

<sup>7</sup>The optional exercises are intended for students who wish to obtain a more complete understanding of various concepts. Some of them are intended to get those interested started on thinking some way beyond the material presented here.

## Academic malpractice

Academic malpractice is a general term that covers a number of ways in which students may break regulations by submitting work as their own which in part is based on unattributed contributions by others.

Note that the rules for collaboration are **different for COMP11120** from almost all other units you may take in the School of Computer Science. Please do not apply them to other units.

We are happy for you to

- try to understand the exercises in a group, including working out how to solve a particular exercise and
- compare your solution to somebody else's.

You **must not**

- copy somebody else's solution (even if you make some changes along the way) or
- give your solution to somebody (either to copy, or adapt, or to take a picture of it) or
- ask to look at somebody else's solution for an exercise which you haven't already solved.

If you are working as a group to understand a particular exercise, then each of you must **write down your own version** of your solution. If you aim to give a counterexample to a statement you should find different counterexamples based on the understanding you gained jointly. If you aim to give a proof then each of you should independently formulate your understanding, and you should not agree on using specific variable names, for example. Students who submit identical (or very similar) answers will be penalized.

If you and another student have solved an exercise independently then we are happy for you to compare your solutions, and if you think the solutions are different you should try to work out between you whether they are both correct, and why. If one of you has an incorrect solution, and the other solution is deemed correct, then the first student may change their solution, but this **must not be done** by merely copying the correct version. Instead the student should start from their incorrect solution and adjust that. Similarly, you **must not let another student copy** your solution, even if you feel sorry for them. They will get at least one mark for their incorrect attempt, and if they've understood what was wrong they should be able to fix their solution for two marks.

Where one student has solved an exercise and another hasn't it is fine for the first to explain how to tackle the questions, to give tips for how to find the solution, and to explain the concepts involved. In a situation like this it is not okay to show your solution to the other student.

Remember also that you have to be able to explain your solution to get the marks, and that identical write-ups will be treated as copying.

## These notes

You will receive a number of handouts over the course of the academic year, referred to here as ‘these notes’. They are a text book in the making which I have written because there is currently none that covers the material required for our programmes at a suitable level of detail. They will cover the following topics:

- complex numbers,
- statements and proofs,
- logic,
- recursion and induction,
- relations,
- linear algebra (vectors and matrices).

These notes have been tailored specifically to the curriculum in computer science here at the University of Manchester. They can be read on a number of levels, and are meant to accompany you through your time here, allowing you to go back and reread material as it becomes relevant to your studies in one of the more advanced course units.

The notes were new for the academic year 2014/15, and have been revised again for 2015/16. Nonetheless there is doubtlessly room for improvement. We would like to invite you to email us if you have suggestions, for example

- if you think you have found a mistake,
- if you think that there is a passage that is misleading,
- issues that require more detailed explanations,
- issues that require more worked examples,
- exercises whose instructions are unclear,
- examples and exercises that we should think about adding,
- online resources you have found useful.

We will certainly incorporate such suggestions for future years, but if there is a particularly important issue, or one where we get several requests, we may hand out supplementary notes as term progresses. We also use interactions with you in examples classes and lectures to guide us, but we would very much appreciate receiving emails on this topic.

We would like to thank Graham Gough, Jonas Lorenz, Joe Razavi, Francis Southern, Yegor Guskov, Francisco Lobo, Sarah Nogueira, Chris Tedd, Luca Minciullo, David Pauksztello, Sami Alabed, Anuj Vaishnav, Ruba Alassaf, Andrew Webb and Andrei Vintila for helping us improve these notes. Some of the ideas for operations on lists come from notes originally written for COMP112 by David Lester, and the idea of including recursively defined functions for natural numbers is based on notes by Graham Gough

for a previous version of this course. Some of the examples and exercises used have been inspired by a variety of sources, but most were specifically created for these notes. In particular some ideas for the probability part of this course were inspired by reading Kees van Schaik's notes for a previous version of this unit.

## Additional literature

There is no book that covers all the material in these notes. They have been specifically written for computer science students going through the curriculum here in Manchester and they cover some material that is not present in most text books. Nonetheless it can be beneficial to look at an alternative presentation of material, and we suggest some books you may want to try for this purpose. These are all present in the departmental as well as the university library for you to borrow. There are certainly other books available that cover much of the material, and you will also find the internet a useful resource on specific topics.

Here is an account of what is covered in which of the suggested books.

- **Basics.** If you find the material in this chapter difficult you should use resources on the web to help you, and maybe also get some of the books below and read about the relevant part.
- **Complex numbers.** This is not covered in most text books aimed at computer scientists, but you will find relevant material in Jordan and Smith. All the operations described in the notes also appear in the Wikipedia article on complex numbers at [https://en.wikipedia.org/wiki/Complex\\_number](https://en.wikipedia.org/wiki/Complex_number), and there are a number of webpages available that aim to explain the general ideas.
- **Statements and proofs.** The definitions and many of their properties are covered in Epp, some of them also in Truss. All the definitions have entries on Wikipedia, and in many other online sources. (for example, the notion of a commutative operation is explained at [https://en.wikipedia.org/wiki/Commutative\\_property](https://en.wikipedia.org/wiki/Commutative_property) such sources provide an alternative point of view that you may find helpful.
- **Logic.** We will not be following any particular text books, but Truss and Epp contain chapters that cover formal logical systems, in particular, the basics of Boolean semantics and properties of propositional formulas. Again you can use a search engine to find additional material on each topic on the web.
- **Probability** This subject is addressed to some extent in Epp, and also in Jordan and Smith, but less generally than in these notes.
- **Recursion and induction.** Recursion and induction are both covered in Epp as well as in Truss, but not at the same level of generality. There are many resources available on the web, for example the Wikipedia article on structural induction here [https://en.wikipedia.org/wiki/Structural\\_induction](https://en.wikipedia.org/wiki/Structural_induction).

- **Relations.** Relations are covered in both, Epp and Truss, and there are many online resources.
- **Linear algebra.** Again there is no text book which covers the material exactly in the way we do. Truss has some material on vectors and matrices, but it is quite condensed. Additional pointers to literature are given in that part of the notes.

Writing about mathematics is difficult, and in particular this holds for giving rigorous arguments. The following book gives a lot of good advice on that subject:

Kevin Houston, **How to Think Like a Mathematician**, *Cambridge University Press*, 2009, ISBN: 052171978X.

Here are some text books on mathematics for computer scientists that you may want to consult in addition to these notes.

Susanna Epp. **Discrete Mathematics with Applications**, *Brooks/Cole* 2011, ISBN: 0495826162.

This book covers much of our material as well as significant parts of COMP11212. It is available online via the university library.

J.K. Truss. **Discrete mathematics for Computer Scientists**, *Addison-Wesley*, 1999. ISBN: 0201360616

This book covers roughly the same material as the first, but with fewer applications, and in slightly less detail.

D.W. Jordan and P. Smith. **Mathematical techniques: an introduction for the engineering, physical, and mathematical sciences**, *Oxford University Press* 2008, ISBN: 9780199282012.

Much of this book is concerned with continuous mathematics, so if you need a refresher it may well be useful for that purpose beyond what is said above.

D. C. Montgomery and George C. Runger. **Applied statistics and probability for engineers (5th edition)**, *Wiley* 2010, ISBN: 978047050578.

This is a very applied text which may help you with connecting the concepts taught here with applications.

E. Angel, **Interactive computer graphics: a top-down approach using OpenGL**, *Pearson* 2008, ISBN: 9780321549433.

This book connects the material on matrices and vectors with the intended application in computer graphics.

All these books are available in the School Library, as well as in the University Library.

# Chapter 0

## Basics

This chapter explains some concepts most of which you should have encountered before coming to university; but you may not have been given formal descriptions previously. These notions give us a starting point so that we have examples for the formal development that follows from Chapter 1 onwards, but note that some of the concepts and properties that appear in this chapter are put on a formal footing subsequently.

Whenever you find concepts used in the notes that have familiar names you should check this chapter to ensure that you only use the fact provided here. There will be no lectures about the material in this chapter, but the examples classes in Week 1 are there to make sure you understand the ideas and the notation used here. Note that there is a universally accepted language described here that you will also encounter in other course units.

Note that we here assume that certain collections of numbers, with various operations, have already been defined. You will see formal definitions of most of these (real numbers being the exception) in Chapter 6 which we will study in Semester 2. The purpose of assuming they are present at the start is to allow us to use them as examples.

### 0.1 Numbers

Naively speaking, numbers are entities we often use when we wish to calculate something. Mathematically speaking, there is typically rather more going on: Numbers are sets with operations, and these operations have particular properties. Many of these properties are named and studied in Chapter 2.

#### 0.1.1 Natural numbers

The **natural numbers** are often also referred to as *counting numbers*, and the collection of all of them is typically written as  $\mathbb{N}$ . For the time being we assume that you know what these numbers are; a formal definition appears as Definition 49 in Chapter 6.

Foreshadowing the formal definition, we point out that simplest way of formally describing the natural numbers is to say that

- there is a natural number 0 and

- given a natural number  $n$  there is another natural number  $S_n$ , the successor of  $n$ , more usually written as  $n+1$ .

Every natural number can be generated in this way, although to reach 123456, for example, one has to apply the successor operation quite a few times! This also means that given a natural number  $n$ , we know that one of the following is the case:

- either  $n = 0$  or
- there exists a natural number  $m$  with  $n = Sm$  (or, if you prefer,  $n = m + 1$ ).

This might seem like a trivial observation, but it is the basis of using the concept of *recursion* to define properties or functions for the natural numbers, and also for being able to prove properties by *induction*.

This is described in detail in Section 6.4 of these notes. Here we look at the informal notions you have met at school.

With the natural numbers come some operations we use; their properties are given below.

- Given natural numbers  $m$  and  $n$  we can add<sup>1</sup> these to get

$$n + m,$$

- Given natural numbers  $m$  and  $n$  we can multiply<sup>2</sup> these to get

$$m \cdot n,$$

You are allowed to use the following about natural numbers, except in Section 6.4 where we prove many of these facts formally.

### Fact 1

Given  $k$ ,  $m$ , and  $n$  in  $\mathbb{N}$  we have<sup>3</sup>

$m + n = n + m$	commutativity of +
$(k + m) + n = k + (m + n)$	associativity of +
$m + 0 = m = 0 + m$	0 unit for + .

For the same variables we also have<sup>4</sup>

$m \cdot n = nm$	commutativity of ·
$(k \cdot m) \cdot n = k \cdot (m \cdot n)$	associativity of ·
$m \cdot 1 = m = 1 \cdot m$	1 unit for · .

For the same variables we also have the property

$$k \cdot (m + n) = k \cdot m + k \cdot n \quad \cdot \text{ distributes over } + .$$

<sup>1</sup>A formal definition of addition appears in Example 6.29.

<sup>2</sup>A formal definition of this operation appears in Example 6.33.

A mathematician might say that the natural numbers form a commutative monoid with unit 0 when looking at the addition operation, and a commutative monoid with unit 1 when looking at multiplication. In Section 2.4 we look formally at the properties given by these equalities.

There is one additional property we require. The following is used in *Euclid's algorithm*, see Example 6.39, but also to define integer division, see below, which appears in Chapter 2.

### Fact 2

Given  $n$  in  $\mathbb{N}$  and  $m \in \mathbb{N} \setminus \{0\}$  there exist unique numbers  $k$  and  $l$  in  $\mathbb{N}$  such that

- $0 \leq l < m$  and
- $n = km + l$ ,  $\leftarrow$  division euclidienne

We use this fact to define a division operation on natural numbers, known as **integer division**<sup>5</sup>. We define<sup>6</sup>

$$\boxed{n \text{ div } m} \quad \text{quotient}$$

to be the unique number  $k \in \mathbb{N}$  in Fact 2. This is the number of times  $m$  divides  $n$  (leaving a remainder). We define the **remainder for integer division** by setting

$$\boxed{n \text{ mod } m} \quad \text{reste}$$

to be the unique  $l$  from Fact 2. This is the remainder  $n$  leaves when divided by  $m$ .

**Example 0.1.** For example, we have that

$5 \text{ div } 2 = 2$	and	$5 \text{ mod } 2 = 1$
$7 \text{ div } 3 = 2$	and	$7 \text{ mod } 3 = 1$
$9 \text{ div } 3 = 3$	and	$9 \text{ mod } 3 = 0$
$11 \text{ div } 4 = 2$	and	$11 \text{ mod } 4 = 3.$

**Example 0.2.** Note that it is not necessarily the case that

$$m \cdot (n \text{ div } m) = n,$$

for example

$$2 \cdot (3 \text{ div } 2) = 2 \cdot 1 = 2 \neq 3.$$

This is different to the way a division operation is usually defined<sup>7</sup> and that is the reason that this kind of division has a different name, and a different symbol.

<sup>3</sup>Formal proofs of these properties appear in Example 6.32 as well as Exercise 123.

<sup>4</sup>Formal proofs of these as well as the final property are given in Exercise 124.

<sup>5</sup>Sometimes also called *Euclidean division*.

<sup>6</sup>See the following section to see that this idea can be extended to the integers.

<sup>7</sup>See for example the discussion in the Section 0.1.3 on rational numbers below.

### Lemma 0.1

For all natural numbers  $m$  and  $n$ , where  $m \neq 0$ , we have

$$n = (n \text{ div } m) + (n \bmod m).$$

**Exercise 1.** Give an argument that Lemma 0.1 is valid using Fact 2.

### Definition 1: divisible

Given natural numbers  $m \neq 0$  and  $n$   $n$  is divisible by  $m$  or that  $m$  divides  $n$  if and only if there exists an integer  $k$  such that

$$m \cdot k = n.$$

Note that  $m$  divides  $n$  if and only if it is the case that

$$n \bmod m = 0.$$

Il peut diviser  $n$  si il n'y a pas de reste

### Definition 2: even/odd

An natural number  $n$  is even if and only if  $n$  is divisible by 2. Such a number is odd if and only if it is not divisible by 2.

This means that  $n$  is even if and only if

$$n \bmod 2 = 0,$$

pair

and that  $n$  is odd if and only if

$$n \bmod 2 = 1.$$

impair

Note in particular that 0 is an even number.

We might also want to think about which equations we can solve in the natural numbers. Assume that  $m$  and  $n$  are elements of  $\mathbb{N}$ .

For example, we can solve

$$m + x = n,$$

within  $\mathbb{N}$ , provided that<sup>8</sup>  $m$  is less than or equal to  $n$ , which we write as  $m \leq n$ .

We can also solve

$$mx = n,$$

within  $\mathbb{N}$  provided that  $n \bmod m = 0$ . Because of the side conditions required we see that a lot of equations we can write down using the available operations do not have a solution.

We can use the natural numbers to count something, for example the number of instructions in a computer program, or the number of times a program will carry out the body of a loop. This is important to do when we

<sup>8</sup>The solution to such an equation would have to satisfy  $x = n - m$  and this is not always defined.

are trying to estimate how long it may take a program to run on a large-size problem.

There are a lot of natural numbers, namely infinitely many. But by mathematical standards the natural numbers are the smallest infinite set, and there are substantially larger ones. Sets of this size are said to be *countably infinite*. This is formally defined in Section 5.2.

Computer languages do typically *not* implement the natural numbers—instead, a programming language will have support for all natural numbers up to a particular maximum. Nothing truly infinite can be implemented in any real-world computer (but there are theoretical computation devices which have infinite storage). Quite often programming languages have a built-in type for integers instead of natural numbers, as is the case with Java.

### 0.1.2 Integers

A simple way of explaining the integers is that one wants to expand the natural numbers in order to make it possible for every number to have an *inverse* with respect to addition, that is, for every number  $n$  there is a number  $m$ , usually written as  $-n$ , with the property that

$$n + m = 0 = m + n.$$

Defining the integers formally in a way that supports the above idea is quite tricky. Such a description is given in Chapter 6 on page 378. It's fairly easy to describe the elements of this set, called<sup>9</sup>  $\mathbb{Z}$ , once one has the natural numbers, since one can say

$$\mathbb{Z} = \mathbb{N} \cup \{-n \mid n \in \mathbb{N} \setminus \{0\}\},$$

but this does not tell us anything about how to calculate with these numbers. So this does not, mathematically speaking, define the integers with all the operations we customarily use for them.

The **absolute**,  $|m|$ , of an integer  $m$  is defined to be<sup>10</sup>

- $m$  if  $m$  is greater than or equal to 0 and
- $-m$  if  $m$  is less than 0.

We (very rarely) use  $\mathbb{Z}^+$  to refer to those integers<sup>11</sup> which are greater than or equal to 0.

#### Fact 3

The equalities from Fact 1 also hold if the variables are elements of  $\mathbb{Z}$ . Additionally,<sup>12</sup>

for every  $n \in \mathbb{Z}$  there exists a unique  $m \in \mathbb{Z}$  with  $m + n = 0 = n + m$ .

<sup>9</sup>The notation  $\mathbb{Z}$  for the set of integers is very common within mathematics, the letter coming from the German word ‘Zahlen’, or numbers. You may know this set under a different name, but that should not worry you.

<sup>10</sup>See Example 0.27 for a definition of this as a function, although that definition is for real numbers.

<sup>11</sup>This set of numbers is, of course, equivalent to  $\mathbb{N}$ .

We say that this number  $m$  is the **additive inverse for  $n$  with respect to addition**. The number  $-n$  is defined to be the additive inverse of  $n$ .

A mathematician would say that  $\mathbb{Z}$  forms a commutative ring with multiplicative unit 1.

Many people use *subtraction* as an operation. However, it is much preferable to think of this not as an operation, but as

$$n - m$$

being a shortcut for adding the additive inverse of  $m$ ,  $-m$ , to  $n$ —in other words, this is merely a shortcut for

$$n + (-m).$$

Please do not talk about subtraction on this course unit, but about adding additive inverses. The reason this is good discipline is that there are many situations where not all inverses exist,<sup>12</sup> and so you should pause to think whether the operation you wish to carry out is legal.

Fact 2 changes a bit when we use it for integers.

#### Fact 4

Given  $n$  in  $\mathbb{Z}$  and  $m \in \mathbb{Z} \setminus \{0\}$  there exist unique numbers  $k$  and  $l$  in  $\mathbb{Z}$  such that

- $0 \leq l < |m|$  and
- $n = km + l$ .

Hence we may extend the definitions of the operations of mod and div, that come from **integer division** for natural numbers as defined above, to the integers. In other words, for integers  $m$  and  $n$ ,

- $n \text{ div } m$  is the unique  $k$ , and
- $n \text{ mod } m$  is the unique  $l$ ,

from the above fact.

**Example 0.3.** We have that

$$\begin{array}{lll} -5 \text{ div } 2 = -3 & \text{and} & -5 \text{ mod } 2 = 1 \\ 7 \text{ div } -3 = -2 & \text{and} & 7 \text{ mod } -3 = 1 \\ 9 \text{ div } -3 = -3 & \text{and} & 9 \text{ mod } -3 = 0 \\ -11 \text{ div } 4 = -3 & \text{and} & 11 \text{ mod } 4 = 1. \end{array}$$

<sup>12</sup>The formal proof that addition satisfies these properties appears in Section 7.3.6 and Exercise 156 provides proof that multiplication satisfies them.

<sup>13</sup>For example, for the rational, real and complex (see Chapter 1) numbers, the number 0 has no multiplicative inverse. When you study matrices you will see that very few matrices have multiplicative inverses.

### Lemma 0.2

For all integers  $n$ , and all integers  $m \neq 0$ , we have

$$n = m \cdot m = n \text{ div } m + n \text{ mod } m.$$

The notions of evenness and oddness transfer with the same definitions as for natural numbers. Indeed, the definitions given below can be applied to natural numbers viewed as integers, and they will give the same result as the corresponding definition from the previous section.

### Definition 3: divisible

Given integers  $m \neq 0$  and  $n$  we say that  $n$  is divisible by  $m$  or that  $m$  divides  $n$  if and only if there exists an integer  $k$  such that

$$m \cdot k = n.$$

Note that  $m$  divides  $n$  if and only if  $n \text{ mod } m = 0$ .

**Exercise 2.** Use Fact 2 and the formal definition of divisibility and mod to argue that the previous sentence is correct.

### Definition 4: even/odd

An integer  $n$  is even if and only if  $n$  is divisible by 2. Such a number is odd if and only if it is not divisible by 2.

**Exercise 3.** Use Fact 4 and the formal definition of  $bmod$  to argue that a natural number  $n$  is even if and only if  $n \text{ mod } 2 = 0$ , and odd if and only if  $n \text{ mod } 2 = 1$ .

How do the even numbers relate to those numbers which are a multiple of 2? Can you make your answer formal? Do your answers change if  $n$  is an integer?

The fact that every number has an additive inverse means that for  $m$  and  $n$  in  $\mathbb{Z}$  we can solve all equations of the form

$$m + x = n$$

within  $\mathbb{Z}$  without reservations. Indeed, every equation in one variable which involves addition and additive inverses has a unique solution. On the other hand, equations of the form

$$mx = n$$

are still not all<sup>14</sup> solvable within  $\mathbb{Z}$ .

If we accept that there are infinitely many natural numbers then it is clear that there are also infinitely many integers. Because the natural numbers are embedded inside the integers one might assume that there are more of the latter, But actually, this is not a sensible notion of size for sets.

<sup>14</sup>The solution would have to satisfy  $x = m/n$ , and this is not defined for all  $m$  and  $n$ .

Mathematically speaking,  $\mathbb{N}$  and  $\mathbb{Z}$  have the same size, see Section 5.2 for details of what that statement means.

Many programming languages support a data type for the integers. However, only finitely many of them are represented. In Java, for example, integers are given by the primitive type `int`, and range from  $-2^{31}$  to  $2^{31} - 1$ .

**Code Example 0.1.** In Java integer division is implemented. Here is a procedure that returns  $n \text{ div } m$  for integer variables  $m$  and  $n$ ,

```
public static int intdiv (int m, int n)
{
    return n/m;
}
```

while this one returns  $n \text{ mod } m$ .

```
public static int intdiv (int m, int n)
{
    return n % m;
}
```

In the programming language C the language specification does not state what the smallest and greatest possible integers are—different compilers have different implementations here. You have to work out what is safe to use in your system.

### 0.1.3 Rational numbers

One can view the rational numbers, usually written<sup>15</sup> as  $\mathbb{Q}$ , as the numbers required if one wants to have a multiplicative inverse for every number other than 0. But again, giving a formal definition of these numbers is not straightforward if one wants to ensure that all the previous operations are available.

One way of talking about the rational numbers is to introduce the notion of a *fraction*, written as

$$m/n,$$

where  $m$  and  $n$  are integers.

But we cannot define the rational numbers to be the collection of all fractions since several fractions may describe the same rational number: We expect  $2/4$  to describe the same number as  $1/2$ .

Formally we have to define a notion of equality (or equivalence) on fractions, whereby

$$m/n = m'/n' \quad \text{if and only if} \quad mn' = m'n.$$

There is a formal definition of the rational numbers, and their addition and multiplication, on page 381.

---

<sup>15</sup>The name comes from the Italian ‘quoziente’, quotient. We look at why this is in Semester 2, see Section 7.3.

We have quite a bit of structure on  $\mathbb{Q}$ . All the facts for integers still hold, but we get a new property.<sup>16</sup>

### Fact 5

The statements from Fact 3 remain true if all variables are taken to be elements of  $\mathbb{Q}$ . In addition,

for all  $q \in \mathbb{Q} \setminus \{0\}$  there exists  $q' \in \mathbb{Q}$  such that  $q \cdot q' = 1 = q' \cdot q$ .

We say that  $q'$  is the **multiplicative inverse for  $q$** . Every element  $q \neq 0$  has a multiplicative inverse and the standard notation for this element is  $q^{-1}$ .

A mathematician would say that  $\mathbb{Q}$  with addition and multiplication is a **field**.

Many people speak of **division** as an operation on rational (and real) numbers, but again, this is merely a shortcut: Writing

$$q'/q$$

is an instruction to multiply  $q'$  with the multiplicative inverse of  $q$ , that is, it is a shortcut for

$$q' \cdot q^{-1}.$$

The number 0 does not have a multiplicative inverse, and that is why division by 0 is not allowed. In this course unit, please try not refer to division as an operation, and when you multiply with inverses, always check to ensure these exist.

**Exercise 4.** What properties would a multiplicative inverse for 0 have to satisfy? Argue that one such cannot exist.

The notion of the **absolute** can be extended to cover the rationals, using the same definition.

Given  $q$  and  $q'$  in  $\mathbb{Q}$  we can now solve all equations of the form

$$q + x = q' \quad \text{and} \quad qx = q' \quad (\text{if } q \neq 0)$$

within  $\mathbb{Q}$ , provided that,<sup>17</sup> for the second equation,  $q \neq 0$ . And indeed, every equation with one unknown involving **addition**, **multiplication** and **inverses** for these operations is solvable provided that it is not equivalent to one of the form  $qx = q'$  where  $q = 0$ ,  $q' \neq 0$ .

The rational numbers are sufficient for a number of practical purposes; for example, to measure the length, area, and volume of something to any given precision, and also to do calculations with such quantities.

There are infinitely many rational numbers, but mathematically speaking,  $\mathbb{Q}$  has the same size as  $\mathbb{N}$ . See Section 5.2 for how to compare the size of sets.

Most mainstream programming languages do not have a datatype for the rationals (or for fractions), but those aimed at algebraic computations (such as Mathematica and Matlab) do.

<sup>16</sup>Exercises 156 and 157 provide formal proofs of most of these properties.

<sup>17</sup>Note how the restrictions we have to make on equations to ensure they are solvable connect with where the operations involved are defined (or not) for the various sets of numbers discussed here.

### 0.1.4 Real numbers

The rational numbers allow us to measure anything up to arbitrary precision, we may add and subtract them, and there are additive and multiplicative inverses (the latter with the exception of 0), which allows us to solve many equations. Why do we need a larger set of numbers?

There are several approaches to this question. Here we give two. If we look at the rational numbers drawn on a line then there are a lot of gaps.

Mathematically speaking we may define a *sequence* (of rational numbers), that is a list of numbers

$$x_n \in \mathbb{Q}, \quad \text{one for each } n \in \mathbb{N}.$$

Sometimes a sequence can be said to *converge to a number*, that is, the sequence gets arbitrarily close to the given number and never moves away from it.<sup>18</sup> If such a number exists it is called the *limit of the sequence*. For example, the limit of

$$1, 1/2, 1/4, 1/8, \dots \quad \text{that is} \quad 1/2^n \text{ for } n \in \mathbb{N}$$

is 0.

Let us consider the sequence defined as follows:

$$\begin{aligned} x_0 &= 1 \\ x_{n+1} &= \frac{x_n^2 + 2}{2x_n} \end{aligned}$$

We may calculate the first few members of the sequence to get

$$1, 3/2, 17/12, 577/408, \dots$$

and, if expressed in decimal notation,

$$1, 1.5, 1.4\bar{1}, 1.4142568627451, \dots$$

One may show that

$$x_n^2$$

gets closer and closer to 2, so we may think of the above as approximating a number  $r$  with the property that  $r^2 = 2$ .

**Optional Exercise 1.** Show that there is no rational number  $q$  with the property that  $q^2 = 2$ . Hint: Assume that you have  $q = m/n$  for some natural numbers  $m$  and  $n$  and derive a contradiction.

Hence there are numbers that are approximated by sequences of rational numbers which are not themselves rational. Or, if we draw the rational numbers as a line then it has a lot of gaps.

One can define the notion of a *Cauchy sequence*. One may think of this as a sequence that should have a limit (because the sequence contracts to a smaller and smaller part of the rational numbers), but where there is no suitable rational number for it to converge to. One can define the **real**

---

<sup>18</sup>This can be defined mathematically but would take up more space than we want to give it here.

**numbers**  $\mathbb{R}$  as being all the limits for all the Cauchy sequences one can build from the rationals. This gives a ‘complete’ set of numbers in the sense that every Cauchy sequence built from elements of  $\mathbb{R}$  has a limit in  $\mathbb{R}$ . We use  $\mathbb{R}^+$  to refer to those real numbers which are greater than or equal to 0. The numbers in  $\mathbb{R} \setminus \mathbb{Q}$  are known as the *irrational numbers*.

We do not give a formal definition of the real numbers in these notes—the above outline should convince you that this is reasonably complicated to do rigorously. We may think of the rational numbers as being included in  $\mathbb{R}$ . The real numbers again come with the operations of addition and multiplication, and inverses for these (but 0 still does not have a multiplicative inverse), and we again have the previous distributivity law for these operations. Just like the rational numbers, the reals with these operations form a *field*, see Fact 6.

An alternative approach to introducing numbers beyond the rationals is as follows. Within the rational numbers we are able to solve all ‘sensible’ equations in one variable involving addition, multiplication and their inverses with rational numbers. We may even add multiples of that variable with each other.<sup>19</sup> But we may not multiply the unknown with itself: Equations of the form

$$xx = q \quad \text{or} \quad x^2 = q$$

are not all solvable with  $\mathbb{Q}$ . By moving from  $\mathbb{Q}$  to  $\mathbb{R}$  we add a lot of solutions to such equations to our set of numbers. For example, all equations of the form

$$x^n = r$$

are solvable for  $n \in \mathbb{N}$  and  $r \in \mathbb{R}$  with  $r \geq 0$ . Indeed, we may replace  $n \in \mathbb{N}$  by  $q \in \mathbb{Q}$  and we still have solutions.<sup>20</sup>

The situation becomes quite complicated. First of all we define a new symbol: We write

$$\sum_{i=0}^n a_i x^i = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0$$

for a sum of a finite number of elements.<sup>21</sup>

Given a **polynomial equation**, that is one of the form

$$\sum_{i=0}^n a_i x^i = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0 = 0$$

where  $a_i \in \mathbb{Q}$  for  $0 \leq i \leq n$ , there may be up to  $n$  different solutions, or there may be none at all. Those real numbers that are solutions to such polynomial equations are known as *algebraic numbers*. Examples are  $\sqrt{2}$ ,  $\sqrt[5]{17}$  and  $\sqrt[3]{3/2}$ .

But not all elements of  $\mathbb{R}$  can be written as solutions to such equations. Those that can not are the *transcendental numbers*; famous examples are  $e$

---

<sup>19</sup>These equations are called *linear*.

<sup>20</sup>And we may even replace  $q \in \mathbb{Q}$  by  $r' \in \mathbb{R}$  and use the idea of the *continuity of a function* to define the operation of forming  $x$  to the power of  $r'$ , and we can still find solutions.

<sup>21</sup>This idea is formally introduced on page 6.42 in Chapter 6 but we use the  $\sum$  symbol in Chapter 4 as well.

and  $\pi$ , and less well-known ones  $e^\pi$  and  $2\sqrt{2}$ . We can therefore *not*<sup>22</sup> use the idea that  $\mathbb{R}$  arises from  $\mathbb{Q}$  by adding solutions to equations over  $\mathbb{Q}$  to formally define  $\mathbb{R}$ .

### Fact 6

All statements from Fact 5 remain true if the variables are taken to be elements of  $\mathbb{R}$ .

A mathematician would say that the real numbers, with addition and application, also from a field.

All the sets of numbers discussed so far are *ordered*, that is, given two numbers we may compare them. See Section 7.4.1 on how one generally talks about this idea. Here we are concerned with giving additional facts you may want to use in solving exercises.

### Fact 7

Let  $r, r', s$  and  $s'$  be elements of  $\mathbb{R}$ . Then the following hold:

For all $r, r' \in \mathbb{R}$	we have	$r \leq r' \text{ or } r' \leq r.$
If $r \leq r'$ and $s \leq s'$	then	$r + s \leq r' + s'.$
If $r \leq r'$ and $s \geq 0$	then	$r \cdot s \leq r' \cdot s.$
If $r \leq r'$ and $s \leq 0$	then	$r \cdot s \geq r' \cdot s.$
If $r \leq s$	then	$-r \geq -s.$
If $r \leq s$	then	$r^{-1} \geq s^{-1}$

The definition of the **absolute** again transfers to this larger set of numbers.

Real numbers are often referred to using *decimal expansions*. Such an expansion is given by an integer together with a sequence of digits (one digit for each natural number). For the integer 0 for example one gets numbers typically written

$$0.d_1d_2d_3\dots,$$

where for  $i \in \mathbb{N}$  we know that  $d_i \in \{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$ . It is common not to write trailing 0s (that is 0s where there is no different digit occurring to the right), so we write 3.14 instead of 3, 14000000.... Note, however, that a number may have more than one decimal expansion, and that 0.9999999... refers to the same number as 1.0000000... = 1.

We don't really need real numbers in the 'real world', but a lot of what we might want to describe becomes a lot smoother if we are allowed to use them (the trajectory of a ball is much easier thought of as a line than a sequence of points with rational coordinates), and they allow us to be precise when referring to the circumference of a circle, for example.

The set  $\mathbb{R}$  is infinite in size—but mathematically speaking, it is strictly larger than  $\mathbb{Q}$ . It is *uncountably infinite*. See Section 5.2 for more details.

No real-world computer can implement all the real numbers. This is no surprise given that there are infinitely many of them. But more importantly

<sup>22</sup>There is a way of algebraically defining the real numbers, but that requires a lot of mathematical theory to be set up that is fairly advanced.

every implementation of (some of) the real numbers will only allow limited precision.<sup>23</sup> Programming languages typically have some kind of *floating point number* type to approximate real (and so also) rational numbers, such as `float` in Java. It's not unusual for there to be a more precise type, such as `double` in Java. Note that operations on such numbers typically incur *rounding errors* (for these operations to be precise it would be necessary to change the range of numbers which are representable by adding more digits—for example,  $.5/2.0 = .25$ , and we need to go from 1 digit after the decimal point to 2). In Java there is also *bignum* which allows for arbitrary precision (since the maximal allowable length of the number can be extended), provided the number has a finite decimal expansion, but these come at a price in memory and time performance (and a program that keeps adding digits will eventually run out of memory). Floating point numbers are given by a *significand* and an *exponent* (because this increases the range of numbers that can be represented), where for a given base, the number described is

$$\text{significand} \times \text{base}^{\text{exponent}}.$$

### 0.1.5 Numbers

We typically think of the sets of numbers introduced here as being subsets of each other, with

$$\mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q} \subseteq \mathbb{R}.$$

Mathematically speaking, this is not strictly correct, but instead we have a function that embeds the integers, say, in the rationals, in such a way that carrying out operations from the integers also works if we think of the numbers as rationals. See Section 7.3.6 for a formal definition of the integers and the rational numbers.

Sometimes in these notes we do not want to specify which set of numbers we mean, and then we assume there is a set

$$N \quad \text{with} \quad \mathbb{N} \subseteq N \subseteq \mathbb{R}$$

with an addition and a multiplication operation satisfying Fact 1.

## 0.2 Sets

Sets are very important in mathematics—indeed, modern mathematics is built entirely around the notion of sets.

A **set** is a collection of items. Collections are required in order to

- make it clear what one is talking about (ruling some things in and others out);
- precisely define various collections of numbers—and in general, much of algebra is concerned with structures given by
  - an *underlying set* (for examples see Section 0.1 for various sets of numbers which, however, aren't formally defined here),

---

<sup>23</sup>There are some languages where it is possible to carry out calculations to a pre-defined precision, but these are not main stream, and significant overhead is required to make this work properly.

- operations on the set (such as addition and multiplication, for various collections of numbers) and
- the properties of these operations (see for example Facts 1, 3, 5 and 6).<sup>24</sup>
- define *functions* (see following section)—instructions for turning entities of one kind into entities of another.

Sets have *members* and indeed a set is given by describing all the members it contains. We write

$$s \in S$$

if  $s$  is an member of the set  $S$ . This sounds simpler than it turns out to be. Members are often also referred to as *elements*. There is a set that contains no elements at all, the **empty set**,  $\emptyset$ .

### 0.2.1 Set theory

Deciding which collections of entities may be considered sets is not as easy as it might sound. Originally mathematicians thought that there would not be any problems in allowing any collection to be considered a set, but very early into the 20th century Bertrand Russel described the *paradox* named after him:

If we are allowed to form the set of all sets which contain themselves as members then we have a contradiction.<sup>25</sup> Theories that contain contradictions are called *inconsistent*, and they are not very useful since (at least according to classical logic) every statement may be deduced in an inconsistent theory. But if every statement is valid then the theory is of no use.

This caused something of a crisis, and prompted the creation of **set theory** as a field within mathematics. Set theory is concerned with the question of how sets may be built in a way that does not lead to contradictions. Mathematicians need to build fairly complicated sets, and making sure that all their constructions are allowed in the underlying set theory is not easy. The sets we require on this course unit are nothing like as complicated and so we do not have to worry about proper set theory here (and you should not refer to what is described in this section as ‘set theory’).

### 0.2.2 Operations on sets

The most fundamental operations on sets we may use is to compare<sup>26</sup> them.

#### Definition 5: subset

A set  $S$  is a **subset** of the set  $T$ , written

$$S \subseteq T,$$

if and only if every member of  $S$  is also an member of  $T$ .

<sup>24</sup>These properties are studied in more detail in Section 2.4.

<sup>25</sup>Ask yourself whether the given ‘set’ contains itself.

<sup>26</sup>A more general notion of comparisons between sets is studied in Section 5.2.

In this situation we have

$$s \in S \quad \text{implies} \quad s \in T,$$

or

$$\text{for all } s \in S \quad s \in T.$$

Note that the usage of key phrases such as ‘implies’, ‘there exists’, ‘for all’ is described in detail in Chapter 2.2.1.

If  $S \subseteq T$  and  $T \subseteq S$  then  $S = T$  because they contain precisely the same members.

#### Definition 6: proper subset

We say that a set  $S$  is a proper subset of the set  $T$  if and only if

- $S$  is a subset of  $T$ , that is  $S \subseteq T$  and
- there exists a member  $t \in T$  with  $t \notin S$ ,

Sometimes the notations

$$S \subset T \quad \text{or} \quad S \subsetneq T$$

are used in this situation.

When we have sets we may build new sets by putting their combined members into one set, or by considering only those members contained in both sets. Because constructing new sets is non-trivial and may lead to problems it is usually better first to find an ‘ambient’ set that contains both the given sets.

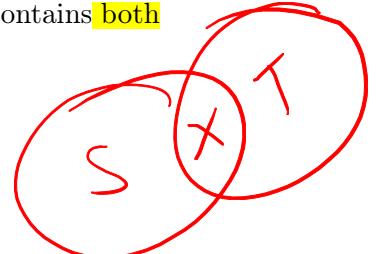

Given a set  $X$ , for  $S$  and  $T$  subsets of  $X$ , we define

- their union,  $S \cup T$ , to be

$$\{x \in X \mid x \in S \text{ or } x \in T\};$$

- their intersection,  $S \cap T$ , to be

$$\{x \in X \mid x \in S \text{ and } x \in T\}.$$

Note that we may now define the union or intersection of finitely many subsets of  $X$  by applying the operation to two sets at a time, that is, for example,

$$S_1 \cup S_2 \cup S_3 \cup \cdots \cup S_n = (\cdots ((S_1 \cup S_2) \cup S_3) \cup \cdots \cup S_n).$$

Again we have used  $\cdots$  here, and to be more precise we should adopt the mathematical notation

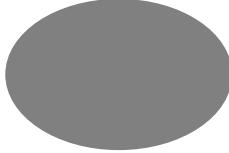

$$\bigcup_{i=1}^n S_i$$

instead, which spells out that we are forming the union of all the sets from  $S_1$  to  $S_n$ .

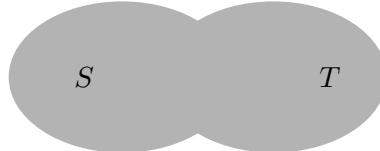

But in fact, given an arbitrary collection of subsets of  $X$  we may define their union and their intersection to obtain another subset of  $X$ .

**Optional Exercise 2.** How could you describe an ‘arbitrary collection of subsets of  $X$ ? Can you come up with a definition of the union of all these sets?

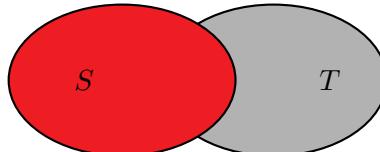

It is sometimes useful to draw such constructions in the form of a **Venn diagram**.

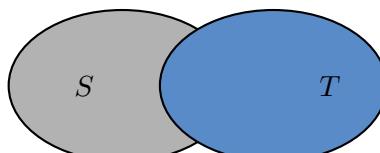

This is a **picture of a generic set**. The union of two generic sets,  $S$  and  $T$ , can then be drawn as follows.

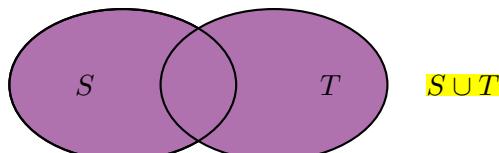

But this is a bit imprecise if we do not draw the boundaries of the sets, so it is more common to draw the boundaries of all the sets involved. We assume we have a set  $S$ , here shown in red,<sup>27</sup>

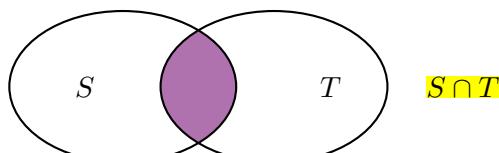

and a set  $T$ , here shown in blue

for which we form the **union  $S \cup T$**  (here in purple).

The picture for the **intersection**, again drawn in purple.

Sometimes we care about the fact that two sets do not overlap.

---

<sup>27</sup>You will see the colours only in the electronic but not in the printed version.

### Definition 7

disjoint We say that two sets  $S$  and  $T$  are **disjoint** if and only if it is the case that

$$S \cap T = \emptyset.$$

There is one further important operation on sets.

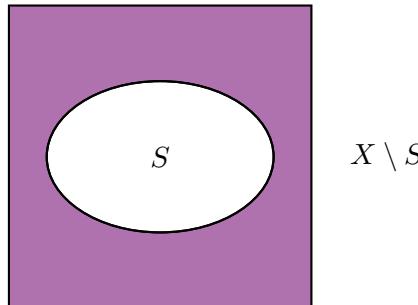

### Definition 8: complement relative to

Let  $S$  be a subset of a set  $X$ . The **complement of  $S$  relative to  $X$** ,  $X \setminus S$ , is given by

$$\{x \in X \mid x \notin S\}.$$

Some people write  $X - S$  for this set, and some people write  $S'$  or  $\bar{S}$ . The latter two require that it is clearly understood which ambient set (here  $X$ ) is meant. It has the advantage that some properties can be formulated very concisely in that notation. We do *not* use the primed version for complement in these notes—instead, we use it to give us variable names (so  $S$ ,  $S'$  and  $S''$  might be names for different sets).

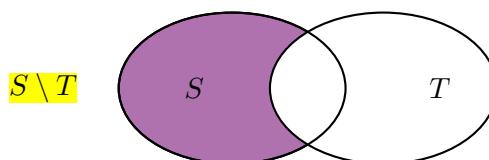

If we want to draw the complement then we *have to* draw the ambient set  $X$ . (We didn't have to do this for the examples so far.<sup>28</sup>) We do this by drawing a square, with  $S$  living inside the square.

These are all the operations required to build new sets from given ones. It is now possible, for example, to **define the set difference**,  $S \setminus T$ , of all members of  $S$  that do not belong to  $T$ ,

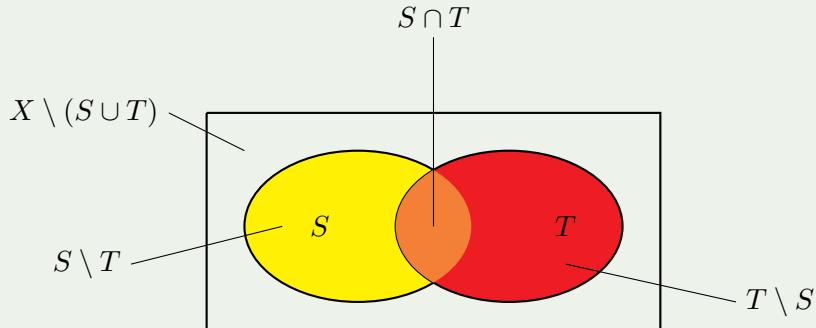

$$\begin{aligned} S \setminus T &= \{s \in S \mid s \notin T\} \\ &= S \cap (X \setminus T), \end{aligned}$$

drawn in purple below.

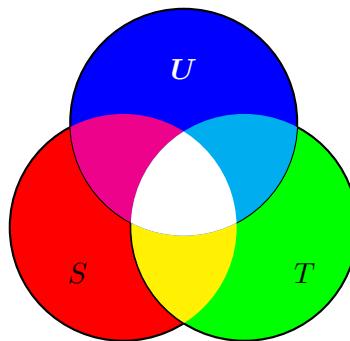

<sup>28</sup>We could have drawn a box around the diagrams given above, but this doesn't really add anything.

**Example 0.4.** We can use these operations to give names relative to  $S$  and  $T$  to all the regions in the following picture. This means we know how to determine the elements of all these regions, provided we know when an element is in  $S$ , and when it is in  $T$ .

If we have more than two sets to start with then there are many more sets one could describe, but we now have tools to do so for all of them.

**Exercise 5.** Identify all regions in the above picture and give their description based on operations applied to  $S$ ,  $T$ , and  $U$ .

**EExercise 6.** Assume that  $S$  and  $T$  are subsets of a set  $X$ .

- Show that the complement relative to  $X$  of the union of  $S$  and  $T$  is the intersection of the complements (relative to  $X$ ) of  $S$  and  $T$ . Hint: Turn the sentence into an equality of sets.
- Show that the union of two sets may be written using only the complement and the intersection operations. Hint: Use your equality from the previous part.
- Given an argument that we may describe precisely the same sets using  $(\cup, \cap$  and  $\setminus$ ) as using  $(\cap$  and  $\setminus$ ).

A useful operation assigns to a finite set the number of elements in that set, which is written as<sup>2930</sup>

$$S \longmapsto |S|.$$

<sup>29</sup>Some texts may use  $\#S$  instead.

<sup>30</sup>If you are not familiar this notation to describe a function come back to this once you have read Section 0.3.

### 0.2.3 Describing sets

Describing sets precisely is harder than it may sound. If a set has finitely many elements then, in principle, we could list them all. But if there are a lot of them this is rather tedious and time-consuming. People often resort to using ... to indicate that there are members that are not explicitly named, and they hope that it is clear from the context what those members are. Take for example

$$\{0, 1, 2, \dots, 100,000\}.$$

Bad

But whenever this notation is used there is room for confusion. It is much better to give a more precise description such as

$$\{n \in \mathbb{N} \mid n \leq 100,000\}.$$

Good

The idea behind this kind of description is that one describes the set in question as a *subset of a known set* (here  $\mathbb{N}$ ), consisting of all those members satisfying a particular *property* (here being less than or equal to 100,000). In logic such a property is known as a *predicate*. It is almost inevitably the case that any set we might want to describe is a subset of a set already known, so this technique works remarkably often.

**Example 0.5.** Let's assume we want to describe the set of even natural numbers. We could write

$$\{0, 2, 4, 6, \dots\},$$

but this leaves it to the reader to make precise which elements belong to the set and which ones don't. This is strongly discouraged. Instead we could write the preferable

$$\{n \in \mathbb{N} \mid n \text{ even}\},$$

but that assumes that the reader knows how the even property is defined. If we want to leave no room for doubt we could apply the definition (see Definition 4) and write

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0\}.$$

This makes it precise which members belong to our set—indeed, it gives us a test that we can apply to some given natural number to see whether it belongs to our set.

**Example 0.6.** Because we may form intersections and unions of sets we may also specify sets consisting of all those elements which have more than one property. All even numbers up to 100,000 could be described as an intersection, namely

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0\} \cap \{n \in \mathbb{N} \mid n \leq 100,000\},$$

but it is more customary instead to combine both properties by using

'and', that is

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0 \quad \text{and} \quad n \leq 100,000\}.$$

When looking at the **real numbers** there is a **standard way of defining subsets** which give a contiguous part of the real line:

$$[x, y] = \{r \in \mathbb{R} \mid x \leq r \leq y\}$$

and

$$(x, y) = \{r \in \mathbb{R} \mid x < r < y\},$$

or

$$[x, y) = \{r \in \mathbb{R} \mid x \leq r < y\},$$

but also

$$(-\infty, y] = \{r \in \mathbb{R} \mid r \leq y\}.$$

Sets of this form are known as '**real intervals**'. Note that we use the notation

$$\mathbb{R}^+ = [0, \infty),$$

for **non-negative real numbers**.

We may also use the idea of **defining sets** using properties to describe all those elements of a given set which satisfy at least one of several properties.

**Example 0.7.** An example of this idea is given by

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0 \quad \text{or} \quad n \bmod 2 = 1\},$$

which is the **union of two sets**, namely

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0\} \cup \{n \in \mathbb{N} \mid n \bmod 2 = 1\},$$

and this set is equal to  $\mathbb{N}$ .

**Example 0.8.** It is also possible to use this idea to specify the elements that *do not* have a particular property. The **odd natural numbers** are those that are not even.

$$\begin{aligned} \{n \in \mathbb{N} \mid n \bmod 2 \neq 0\} &= \mathbb{N} \setminus \{n \in \mathbb{N} \mid n \bmod 2 = 0\} \\ &= \{n \in \mathbb{N} \mid n \bmod 2 = 1\}. \end{aligned}$$

**Example 0.9.** Of course these ideas do not merely apply to natural numbers. We can start from any set that has been previously defined. For example, if we want to describe the rational numbers as a subset of  $\mathbb{R}$  we may use

$$\{r \in \mathbb{R} \mid \text{there exists } m \text{ and } n \text{ in } \mathbb{Z} \text{ such that } r = m/n\},$$

Note that we might describe sets without elements.

**Example 0.10.** Nothing stops us from specifying

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0 \text{ and } n \bmod 2 = 1\},$$

which is a rather complicated description of the empty set.

It is possible to use infinitely many restricting properties.

**Example 0.11.** Given a natural number  $k$ , the multiples of  $k$  can be written as

$$\{n \in \mathbb{N} \mid n \bmod k = 0\}.$$

So the set of natural numbers which are not multiples of  $k$  is

$$\{n \in \mathbb{N} \mid n \bmod k \neq 0\}.$$

**Example 0.12.** A more complicated question is how to describe the set of all prime numbers.

For that it helps to consider the set of elements which are not a multiple of any number other than one and themselves, which is equivalent to saying that they are not a multiple of any number with a factor of at least 2.

The set of all multiples of  $k$  in  $\mathbb{N}$ , with a factor of two or greater, is given by

$$\{n \in \mathbb{N} \mid n \bmod k = 0, n \bmod 2 \geq 1\},$$

and the set of all numbers which are not such a multiple is

$$\mathbb{N} \setminus \{n \in \mathbb{N} \mid n \bmod k = 0, n \bmod 2 \geq 1\}.$$

which is the same as

$$\{n \in \mathbb{N} \mid n \bmod k \neq 0 \text{ or } (n \bmod k = 0 \text{ and } n \bmod 2 \neq 1)\},$$

which is the same as

$$\{n \in \mathbb{N} \mid n \bmod k \neq 0 \text{ or } n = k\},$$

This suggests that we can use the intersection of all these sets of non-multiples of  $k$ , where  $k \in \mathbb{N} \setminus \{0, 1\}$ , to express the prime numbers. This set is given by

$$\bigcap_{k \in \mathbb{N} \setminus \{0, 1\}} \{n \in \mathbb{N} \mid n \bmod k \neq 0 \text{ or } n = k\}$$

Instead of restricting the elements of a known set to describe a new set it is sometimes possible instead to provide instructions for constructing the elements of the new set. This is the second important technique for describing sets.

**Example 0.13.** An alternative way of describing the even numbers is to recognize that they are exactly the multiples of 2, and to write

$$\{2n \mid n \in \mathbb{N}\}.$$

The odd numbers may then be described as

$$\{2n + 1 \mid n \in \mathbb{N}\}.$$

But for a better answer, we should add something here. Read on to find out what.

We can think of this as *constructing* a new set, but usually this only makes sense when describing a subset of a previously known set. Certainly the notation assumes that we know what we mean by  $2n$ , or  $2n + 1$ —this implies we know where the addition and multiplication operations that appear in these expressions are to be carried out. In this examples it is in  $\mathbb{N}$ , so it would be better to write

$$\{2n + 1 \in \mathbb{N} \mid n \in \mathbb{N}\}.$$

This may seem obvious, since  $\mathbb{N}$  is explicitly named as the set  $n$  belongs to, but assume that in order to describe the rational numbers we wrote

$$\{m/n \mid m, n \in \mathbb{Z}, n \neq 0\}.$$

But what does this mean? Where do we take  $m/n$ ? This is not defined in the collection  $\mathbb{Z}$  of numbers where  $m$  and  $n$  live, and so it is not clear what we mean here. Maybe this is a set of formal fractions? We could clarify this by writing

$$\{m/n \in \mathbb{R} \mid m, n \in \mathbb{Z}, n \neq 0\},$$

from which it is clear that we we mean to collect all the results of calculating  $m \cdot n^{-1}$  within the real numbers.

**Example 0.14.** To describe the integer multiples of  $\pi$  (for example if we want to have all the points on the real line for which sin takes the value 0) we might write,

$$\{n\pi \mid n \in \mathbb{Z}\}.$$

Again we have to deduce from the context where  $n\pi$  is meant to be carried out. If we write

$$\{n\pi \in \mathbb{R} \mid n \in \mathbb{Z}\},$$

then everything is made explicit.

**CExercise 7.** For the sets given below, give a description using a predicate (as in Example 0.5), and also give a description where you generate the set (as in Example 0.13).

- (a) Describe the set of all integers that are divisible by 3.
- (b) Describe the set of all integers that are divisible by both, 2 and 3.

- (c) Describe the set of all integers that are divisible by 2 or by 3. To generate this set you need to use the union operation.
- (d) Describe the set of all integers that are divisible by 2 or by 3 but not by 6. To generate this set you need to use the union, and the relative complement, operations.
- (e) Describe the set of all real numbers  $r$  for which  $\cos r = 0$ .

#### 0.2.4 Constructions for sets

There is one other fairly common construction for sets.

##### Definition 9: product of two sets

Given sets  $X$  and  $Y$  their<sup>31</sup> product is the set

$$\{(x, y) \mid x \in X \text{ and } y \in Y\}.$$

This means that the elements of the product are pairs whose first component is an element of  $X$  and whose second component is an element of  $Y$ . Products of sets appear in many places, and the examples we give below barely scratch the surface.

**Example 0.15.** The product of the set  $\{0, 1\}$  with itself is the set with the elements

$$(0, 0), (0, 1), (1, 0), (1, 1),$$

so

$$\{0, 1\} \times \{0, 1\} = \{(0, 0), (0, 1), (1, 0), (1, 1)\}.$$

**Example 0.16.** A more familiar example is a deck of cards: You have four suits, clubs ♣, spades ♠, hearts ♥ and diamonds ♦, and you have standard playing cards, say 7, 8, 9, 10, J, Q, K, A in a 32-card deck. Each of those cards appears in each of the suits, so you have four Queens, one each for clubs, spaces, hearts and diamonds. In other words, your 52-card deck can be thought of as the product

$$\{\clubsuit, \spadesuit, \heartsuit, \diamondsuit\} \times \{7, 8, 9, 10, J, Q, K, A\}.$$

We can picture the result as all combinations of elements from the first set with elements from the second set.

	7	8	9	10	J	Q	K	A
♣	7♣	8♣	9♣	10♣	J♣	Q♣	K♣	A♣
♠	7♠	8♠	9♠	10♠	J♠	Q♠	K♠	A♠
♥	7♥	8♥	9♥	10♥	J♥	Q♥	K♥	A♥
♦	7♦	8♦	9♦	10♦	J♦	Q♦	K♦	A♦

Whenever you draw the graph of a function from  $\mathbb{R}$  to  $\mathbb{R}$  you do so in the product of the set  $\mathbb{R}$  with itself: You use the  $x$ -axis to give the source

<sup>31</sup>This is also known as their Cartesian product.

of the function, and the  $y$ -axis for the target, and you then plot points with coordinates  $(x, fx)$ , where  $x$  varies through the source set.

**Example 0.17.** A very important set that is a product is the *real plane*

$$\mathbb{R}^2 = \{(r, r') \mid r, r' \in \mathbb{R}\}.$$

This is the set we use when we draw the graph of a function from real numbers to real numbers (see Section 0.3.4), where we use the first coordinate to give the argument, and the second argument to give the corresponding value.

**Example 0.18.** Similarly, the  $n$ -dimensional vector space based on  $\mathbb{R}$  has as its underlying set the  $n$ -fold product of  $\mathbb{R}$  with itself,

$$\mathbb{R}^n = \{(r_1, r_2, \dots, r_n) \mid r_1, r_2, \dots, r_n \in \mathbb{R}\}.$$

In general, if  $S$  is a set, people often write

$$S^2$$

for

$$S \times S$$

and more generally,

$$S^n$$

for the  $n$ -fold product of  $S$  with itself. The elements of this set can be described as  $n$ -tuples of elements of  $S$ , that is

$$S^n = \{(s_1, s_2, \dots, s_n) \mid s_i \in S \text{ for } 1 \leq i \leq n\}.$$

Note that here we construct a new set, and we define what the elements of the set are (namely pairs of elements of the given sets) and we do not have to identify an ambient set.

In Section 2.4 we describe operations on sets as functions (see Sections 0.3) and for that we require the product construction. A **binary operation**<sup>32</sup> is one that takes two elements from a set, and returns one element of the same set.

**Example 0.19.** Addition for the natural numbers  $\mathbb{N}$  is a binary operation on the set  $\mathbb{N}$ . As a function (see Section 0.3) it takes two elements, say  $m$  and  $n$ , of  $\mathbb{N}$ , that is

an element  $(m, n)$  of  $\mathbb{N} \times \mathbb{N}$ ,

and returns

an element  $m + n$  of  $\mathbb{N}$ .

The type of this operation is

$$\mathbb{N} \times \mathbb{N} \rightarrow \mathbb{N}.$$

---

<sup>32</sup>That is an operation which takes two numbers and returns a number.

But, of course, we may also consider addition for different sets of numbers, giving operations, for example

$$\mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{Z}$$

$$\mathbb{Q} \times \mathbb{Q} \rightarrow \mathbb{Q}$$

$$\mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}.$$

Another general operation sometimes applied to sets is the **disjoint union** but we do not describe this here.

#### Definition 10: powerset

Given a set  $X$ , its **powerset**  $\mathcal{P}X$ , is given by the set of all subsets of  $X$ .

$$\mathcal{P}X = \{S \mid S \subseteq X\}.$$

All our operations on sets were defined for elements of such a powerset. For example, given an element  $S$  of  $\mathcal{P}X$ , which is nothing but a subset of  $X$ , we have  $X \setminus S$ , the complement of  $S$  with respect to  $X$ , which is another element of  $\mathcal{P}X$ .

**Example 0.20.** We may think of the **union** operation as taking two elements of  $\mathcal{P}X$ , and returning an element of  $\mathcal{P}X$ , so we would write that as

$$\cup: \mathcal{P}X \times \mathcal{P}X \rightarrow \mathcal{P}X.$$

Because there are so many operations on the powerset it turns out to be a useful model for various situations. In the material on logic we see how to use it as a model for a formal system in logic.

Sometimes we care only about the finite subsets of a set, that is

$$\{S \subseteq X \mid X \text{ is finite}\}.$$

People sometimes call this ‘the finite powerset’, but that is a bit problematic since this often isn’t itself a finite set.

## 0.3 Functions

One could argue that sets are merely there to allow us to talk about functions, and while this is exaggerated sets wouldn’t be much use without the ability to move between them.

### 0.3.1 Function, source, target, range

A function is a way of turning entities of one kind into those of another. Formally a **function**

$$f: S \rightarrow T$$

is given by

- a **source set**  $S$
- a **target set**  $T$  and

- an instruction that turns every element  $s$  of  $S$  into an element  $fs$  of  $T$ , often<sup>33</sup> written as

$$s \longmapsto fs.$$

Many people allow giving functions without specifying the source and target sets but this is sloppy. Every function has a type, and for our example  $f$  here the type is  $S \rightarrow T$ .

Some instructions can be used with multiple source and target sets. For example

$$x \longmapsto 2x$$

may be used to define a function

- $\mathbb{N} \rightarrow \mathbb{N}$ ,
- $\mathbb{Z} \rightarrow \mathbb{Z}$ ,
- $\mathbb{Q} \rightarrow \mathbb{Q}$ ,
- $\mathbb{R} \rightarrow \mathbb{R}$ .

and

$$x \longmapsto x^2$$

could have the types (among others)

- $\mathbb{N} \rightarrow \mathbb{N}$ ,
- $\mathbb{Q} \rightarrow \mathbb{Q}$  or  $\mathbb{Q} \rightarrow \mathbb{Q}^+$ ,
- $\mathbb{R} \rightarrow \mathbb{R}$  or  $\mathbb{R} \rightarrow \mathbb{R}^+$ .

### 0.3.2 Composition and identity functions

Which functions we can define from one set to another depends on the structure of the sets, and on any known operations on the sets. Only one (somewhat boring) function is guaranteed to exist for every set  $S$ .

#### Definition 11

identity function The **identity function**  $\text{id}_S$  on a set  $S$  given by the assignment

$$\begin{aligned}\text{id}_S: S &\longrightarrow S \\ s &\longmapsto s.\end{aligned}$$

An important operation on functions is given by carrying out one function after another.

#### Definition 12

composite of two functions Given two functions

$$f: S \rightarrow T \quad \text{and} \quad g: T \rightarrow U$$

---

<sup>33</sup>It is quite often standard to write  $f(s)$  but as long as the argument is not a complicated expression this is unnecessary.

where the target of  $f$  is the source of  $g$ , the **composite of  $f$  and  $g$**

$$g \circ f: S \longrightarrow U$$

$$a \longmapsto g(fa),$$

is defined by first applying  $f$  to  $s$  and then  $g$  to the result, that is

$$s \longmapsto fs \longmapsto gfs$$

$$S \quad T \quad U,$$

and so overall we map  $s \in S$  to  $gfs \in U$ .

Composition allows us to build more complicated functions from simple ones.

**Example 0.21.** One may think of a linear function on  $\mathbb{R}$ , of the form

$$x \longmapsto mx + b$$

to be the result of composing the following two functions  $\mathbb{R} \rightarrow \mathbb{R}$ :

$$f: x \longmapsto mx \quad \text{and} \quad g: x \longmapsto x + b,$$

since this amounts to calculating

In other words, if we apply the function  $f$  to  $x$ , and the function  $g$  to the result, we find that overall  $x$  is mapped to  $mx + b$ .

**Example 0.22.** We use the idea of a composite a lot, but maybe you find it easier to realize this by looking at the assignment

$$x \longmapsto \sqrt{|\sin x|}.$$

This tells you to first apply the sine function to  $x$ , and to apply the square root function to the absolute of the result. The idea of composing functions just makes this explicit, and it also forces you to ensure that the output of the first function is always a valid input to the second function.

**Exercise 8.** Define three functions (not forgetting their sources and targets) such that their composite is a function  $\mathbb{R} \rightarrow \mathbb{R}$  which maps an input to the logarithm (for base 2) of the result of adding 2 to the negative of the square of the sine of the input.

### 0.3.3 Basic notions for functions

It can sometimes be useful to determine which part of the target set is reached by a function.

### Definition 13

Given a function  $f: S \rightarrow T$ , for  $s \in S$  we say that  $fs$  is the image of  $s$  under  $f$ , and

$$\{fs \in T \mid s \in S\}$$

is the range of  $f$ . It is also known as the image of the set  $S$ , and written  $f[S]$ .

Note that we may also write the image of the function  $f$  using a property of elements of  $T$  as

$$\{t \in T \mid \text{there exists } s \in S \text{ with } fs = t\}.$$

range = intervalle de images

**Example 0.23.** For the sine function

$$\sin: \mathbb{R} \rightarrow \mathbb{R},$$

the image of 0 under  $\sin$  is 0, and the range of  $\sin$  is the set

$$[-1, 1].$$

**Example 0.24.** If we formally want to define the notion of a sequence of, say, real numbers, then we should do so as a function  $a$  from  $\mathbb{N}$  to  $\mathbb{R}$ . The  $n$ th member of the sequence is given by  $an$ . In such cases  $an$  is often written  $a_n$ . For example, the sequence given on page 23 would have the first few values

argument	0	1	2	3	4
value	1	1/2	1/4	1/8	1/16

and the formal definition of this function is

$$\begin{aligned} \mathbb{N} &\longrightarrow \mathbb{R} \\ n &\longmapsto \frac{1}{2^n}. \end{aligned}$$

We may also think of a function as translating from one setting to another. In Java casting allows us to take an integer, `int` and cast it as a floating point number, `float`. This is effectively a function which takes an `int` (which amounts to a number of bits) and translates it into what we think of as the same number, but now expressed in a different format.

For a mathematical example, we note that we have functions connecting all our sets of numbers since

$\mathbb{N}$  is embedded in  $\mathbb{Z}$  which is embedded in  $\mathbb{Q}$  which is embedded in  $\mathbb{R}$ .

All these embeddings are functions, but they are so boring that we don't usually bother to even name them. For a slightly more interesting example take the set of all fractions. From there we have a function that maps a fraction to the corresponding rational number (and so  $1/2$  and  $2/4$  are

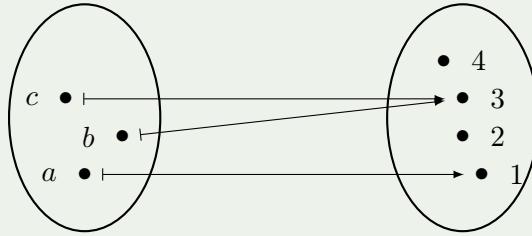

mapped to the same number), allowing us to translate from the presentation as fraction to the numbers we are really interested in.

If you have a customer database you could print a list of all of your customers. You have effectively constructed a function that takes an entry in your database and maps it to the name field. Note that if you have two customers called John Smith then that name will be printed twice, so thinking of a ‘set of names’ is not entirely appropriate here.

If we have small finite sets then one can define a function in a graphical way, by showing which element of the source set is mapped to which element of the target set.

**Example 0.25.** We draw a function

$$\{a, b, c\} \rightarrow \{1, 2, 3, 4\}.$$

This function maps  $a$  to 1 and  $b$  and  $c$  to 3. Note that in order for such a diagram to describe a function, every element of the source set must be mapped to precisely one element of the target set.

### 0.3.4 The graph of a function

It can be useful to think of a function via its graph.

#### Definition 14

The **graph of a function** is the set of pairs consisting of an element of the source set with its image under the function,<sup>34</sup> that is, given

$$f: S \rightarrow T$$

its graph is the set

$$\{(s, fs) \in S \times T \mid s \in S\}.$$

We can see what this definition means by assuming we are given a function

$$f: S \rightarrow T$$

and noting that this definition tells us that is graph is the set

$$\{(s, fs) \in S \times T \mid s \in S\}$$

which is a subset of the product of  $S$  and  $T$ .

See Proposition 2.1 for a characterization of those subsets of  $S \times T$  which are the graph of a function from  $S$  to  $T$ .

---

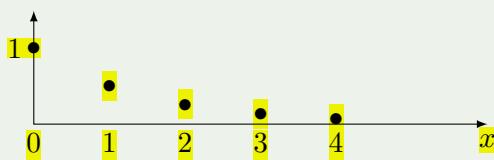

<sup>34</sup>And indeed, a standard way of defining functions in set theory is via their graphs.

When we have functions between sets of numbers we can draw a picture of their graph.

**Example 0.26.** Let's return to the function from Example 0.24, which is given by

$$\begin{aligned}\mathbb{N} &\longrightarrow \mathbb{R} \\ x &\longmapsto \frac{1}{2^x}.\end{aligned}$$

Its graph can be drawn as follows.

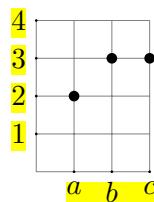

More examples appear in the following section.

For functions between finite sets drawing the graph in this way is usually not particularly useful. The graph of the finite example above is

$$\{(a, 2), (b, 4), (c, 4)\},$$

and one might draw it as follows:

This does not really show anything that is not visible in the previous diagram.

### 0.3.5 Important functions

When we are interesting in judging how long a computer program will take we typically count the number of instructions that will have to be carried out. How many instructions these are will, of course, depend on the program, but also on the *particular input* we are interested in. Often the inputs to a program can be thought of as having a particular size: For example, sorting five variables of type `int` will be quite different from doing so for one million such variables.

Typically the number of instructions a program has to carry out depends on the *size* of the input rather than the actual input, and so we can think of this as defining a function from  $\mathbb{N}$  to  $\mathbb{N}$  which takes the size of the input to the number of instructions that are carried out.

There are a number of functions that typically appear in such considerations.<sup>35</sup> In computer science it would be sufficient for these purposes to

<sup>35</sup>You will meet them again when you look at this in more detail in COMP11212 and COMP26120.

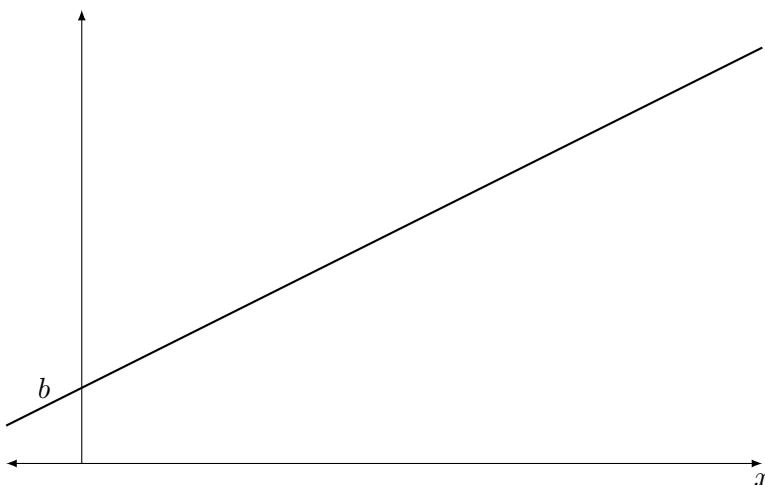

consider these functions as going from  $\mathbb{N}$  to  $\mathbb{N}$ , but it is often more convenient to draw their graphs as functions from  $\mathbb{R}^+$  to  $\mathbb{R}^+$ . In what follows we consider functions that commonly appear in that setting, and where possible we draw their graph as functions from  $\mathbb{R}$  to  $\mathbb{R}$ .

There are linear functions, which are of the form

$$\begin{array}{ccc} \mathbb{R} & \longrightarrow & \mathbb{R} \\ x & \longmapsto & mx + b \end{array}$$

*function  
affine*

and their graphs look like this.

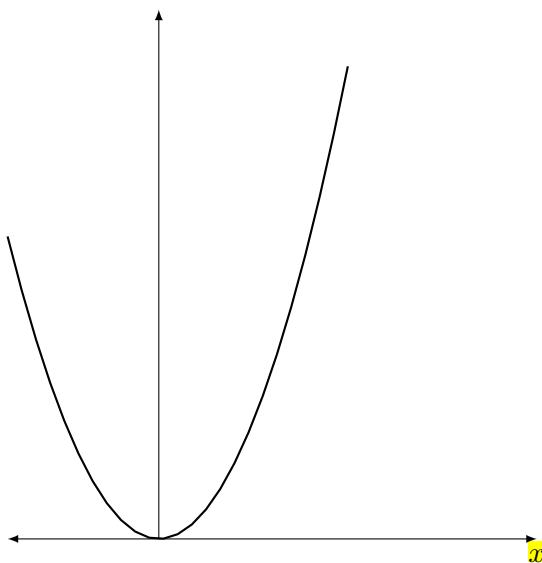

A typical quadratic function is given by

$$\begin{array}{ccc} \mathbb{R} & \longrightarrow & \mathbb{R} \\ x & \longmapsto & ax^2 + bx + c \end{array}$$

*function du  
second degré*

and (assuming that  $a$ ,  $b$  and  $c$  are all in  $\mathbb{R}^+$ ) its graph looks like this:

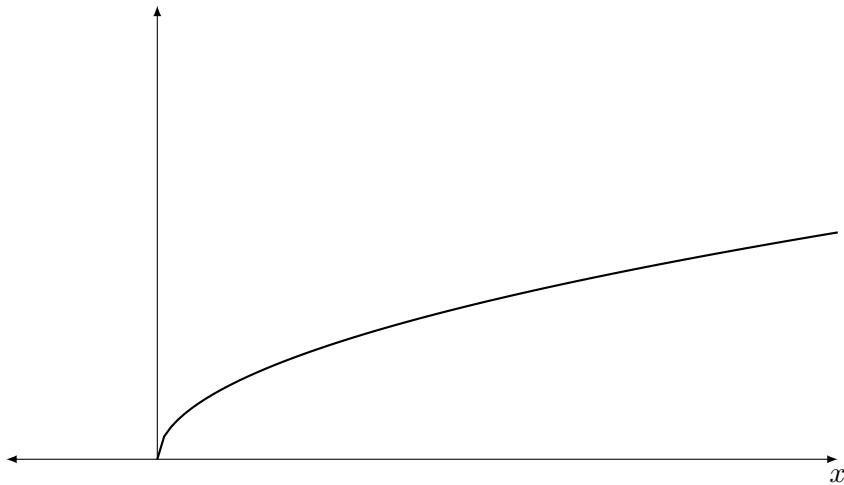

Other polynomial functions, that is functions of the form

$$\sum_{i=1}^n a_i x^i \quad \leftarrow \text{fonction polynôme}$$

may also feature.

Sometimes we wish to consider functions which involve the argument being taken to a power other than a natural number, for example

$$\begin{aligned} \mathbb{R}^+ &\longrightarrow \mathbb{R}^+ \\ x &\longmapsto x^{1/2} = \sqrt{x}. \end{aligned}$$

Some of these functions are defined for non-negative numbers only, so their source is  $\mathbb{R}^+$ , rather than all of  $\mathbb{R}$ . Note that for fixed  $x \in \mathbb{R}^+$  this function only gives the positive solution of the equation

$$y = x^2.$$

If you want to refer to both of these<sup>36</sup> you have to write  $\pm\sqrt{x}$ .

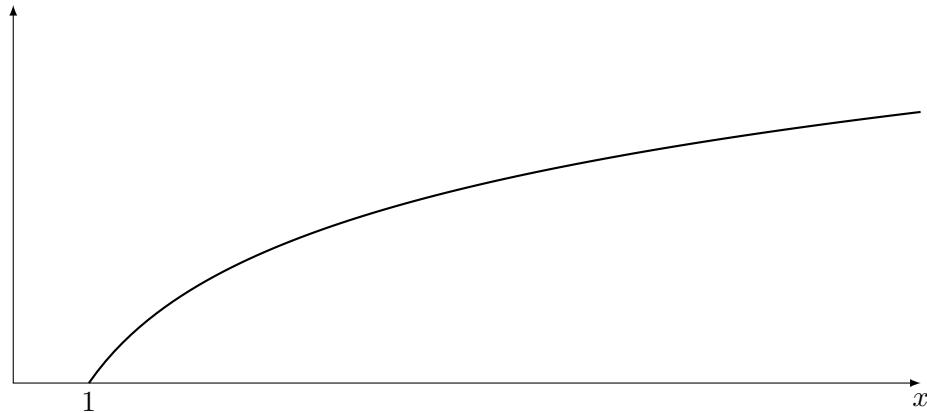

Apart from these polynomial functions, important examples that come up in computer science are concerned with logarithmic functions. In computer science one typically wishes to use logarithms to base 2. They are typically written as

$$\begin{aligned} [1, \infty) &\longrightarrow \mathbb{R}^+ \\ x &\longmapsto \log x \end{aligned}$$

and look like this.

---

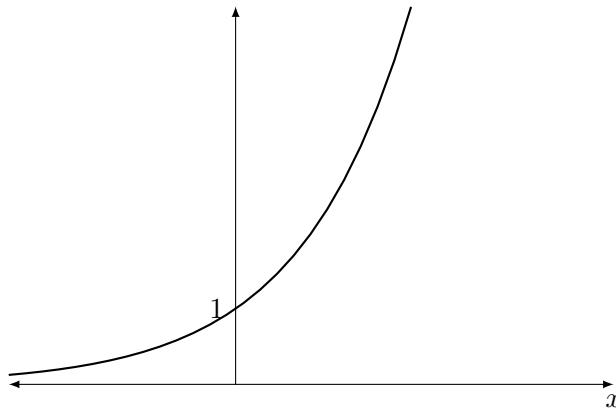

<sup>36</sup>If you have been taught otherwise then this is at odds with notation used at university level and beyond.

And then there are exponential functions. Because of the speed with which these grow having a program whose number of instructions is exponential in the size of the problem is a serious issue since it means that it is not feasible to calculate solutions for larger problem sizes using this program. It is fairly usual to use 2 as a base once again. The function in question is

$$\begin{aligned} \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto 2^x \end{aligned}$$

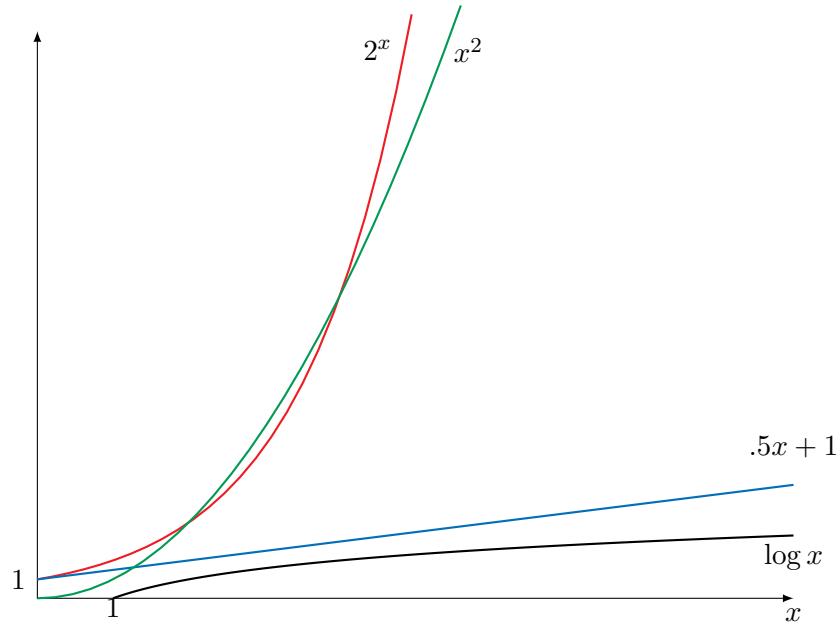

and its graph is even steeper than that of the quadratic curve above.

In all these cases typically the shape of the curve is more important than any parameters involved in defining it—so knowing that we have a quadratic function is very useful, whereas there is little added benefit in knowing  $a$ ,  $b$  and  $c$  in  $ax^2 + bx + c$ .

If one has a problem size of 1,000,000, for example, then it is important to know how fast the function grows to see how many instructions will have to be carried out for that size (and so how long it will take for the program to finish, or if it is possible for this program to finish at all).

If we draw the functions from above in the same grid (note that we have compressed the  $y$ -axis here) we can compare them.

The issue of how to compare functions when we are only interested in how they do for large inputs is discussed in Section 5.1, and this is relevant for calculating the *complexity* of a programme or algorithm.

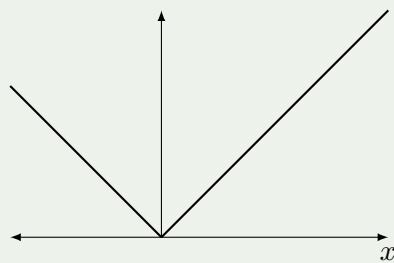

### 0.3.6 Constructions for functions

An important way of constructing new functions from old ones is what is known as **definition by cases**. What this means is that one pieces together different functions to give a new one.

**Example 0.27.** Assume we want to give a proper definition of the ‘absolute’ function

$$|\cdot|: \mathbb{R} \rightarrow \mathbb{R}^+$$

for real numbers. The value it returns depends on whether the input is negative, or not. The graph of this function is depicted here.

We can write the corresponding assignment as

$$x \longmapsto \begin{cases} x & x \geq 0 \\ -x & \text{else.} \end{cases}$$

**Example 0.28.** If you want to give an alternative description of the function

$$\begin{array}{ccc} \mathbb{Z} & \longrightarrow & \mathbb{Z} \\ n & \longmapsto & n \bmod 2, \end{array}$$

which maps even numbers to 0, and odd numbers to 1, you could instead write

$$x \longmapsto \begin{cases} 0 & x \bmod 2 = 0 \\ 1 & \text{else} \end{cases}$$

or, if you don't want to put the mod function into the definition, you could write

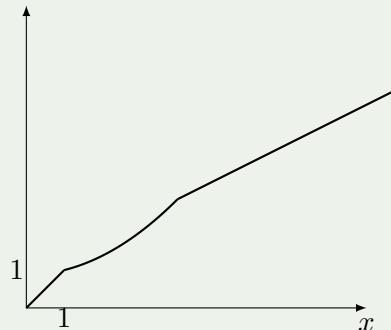

$$x \longmapsto \begin{cases} 0 & x \text{ even} \\ 1 & \text{else.} \end{cases}$$

What is important is that

- you give a value for each element of the source and
- you don't give more than one value for any element of the source.

In other words, on the right you must split your source set into disjoint parts, and say what the function does for each of those parts.

**Example 0.29.** You might need this when you are trying to describe the behaviour of an entity which changes. For example, assume you are given the following graph:

This function  $\mathbb{R}^+ \rightarrow \mathbb{R}^+$  is given by the assignment

$$x \longmapsto \begin{cases} x & x \in [0, 1] \\ \frac{1}{8}x^2 + \frac{7}{8} & x \in (1, 4] \\ \frac{1}{2}x + \frac{7}{8} & \text{else.} \end{cases}$$

**CExercise 9.** Write down formal definitions for the following functions.

- (a) The function which takes two integers and returns the negative of

their product.

- (b) The function from  $\mathbb{R} \times \mathbb{R}$  to  $\mathbb{R}$  which returns its first argument.
- (c) The function from  $\mathbb{Z} \times \mathbb{Z}$  to  $\{0, 1\}$  which is equal to 1 if and only if both arguments are even.
- (d) The function from  $\mathbb{R}$  to  $\mathbb{R}$  which behaves like the sine function for negative arguments, and like the exponential function for base 2 for non-negative arguments.
- (e) Draw a picture of the set

$$\{Abdul, Bella, Clara, Dong\} \times \{red, blue, green\}.$$

Define a function that from that set to  $\{0, 1\}$  which is 1 if and only if its first argument has more letters than its second.

Apart from this, the constructions we have for sets are also meaningful for functions.

If we have functions  $f: S \rightarrow S'$  and  $g: T \rightarrow T'$ . Then we can define a function

$$S \times T \rightarrow S' \times T',$$

which we refer to as

$$f \times g$$

by setting

$$(s, t) \longmapsto (fs, gt).$$

**Optional Exercise 3.** Can you think of something that would allow you to extend the powerset construction to functions?

The following exercises draws on functions, as well as on the definition of the powerset from the previous section.

**EExercise 10.** Given a set  $X$ , define the following functions. Don't forget to write down their source and target.

- (a) A function  $f$  from  $X$  to its powerset with the property that for every  $x \in X$  we have  $x \in fx$ .
- (b) A function from the product of the powerset of  $X$  with itself, to the powerset of  $X$ , with the property that a pair of sets is mapped to the set consisting of all those elements of  $X$  which is either in the first set, or in the second set, but not in both.
- (c) Define a function from the product of  $X$  with its powerset to the set  $\{0, 1\}$  which returns 1 if and only if the first component of the argument is an element of the second component.
- (d) Define a function from the set of finite subsets of  $\mathbb{N}$  to  $\mathbb{N}$  which adds up all the elements in the given set.

## 0.4 Relations

We study relations in detail in Chapter 7. Prior to that chapter, however, relations play a (minor) role in Chapter 3 and we give the basic ideas here for that reason.

Sometimes we have connections between two sets  $S$  and  $T$  which do not take the form of a function. We might have some set of pairs of the form  $(s, t)$ , where  $s \in S$  and  $t \in T$ . Such a set is known as a **binary relation**. Note that relations of other arities exist, but it is customary to drop the ‘binary’ part and just speak of a relation.

**Example 0.30.** Consider the set  $S$  of all the first year students in the School of Computer Science, and the set  $U$  of all course units on offer in the university. We may then define a relation as

$$\{(s, u) \in S \times U \mid s \text{ is enrolled on } u\}.$$

This set is encoded in a database somewhere in the student system.

Relations are very flexible when it comes to capturing connections between various entities. A number of examples are given in Chapter<sup>37</sup> 7, but here are some ideas for the kind of thing that one can do:

- Sometimes a set of interest may contain a number of elements one wishes to consider ‘the same’, for example when using fractions to describe the rational numbers. One may use an *equivalence relation* (between the set and itself) to partition the set into *equivalence classes* and use those instead of the original elements. An example of this is the relation which connects two students if and only if they are in the same lab group.
- One may wish to compare the elements of a set with each other, indicating that one is below another. This is done using a relation between the set and itself known as a *(partial) order*. Examples of these are the usual orders on  $\mathbb{N}$ ,  $\mathbb{Z}$ ,  $\mathbb{Q}$  and  $\mathbb{R}$ , but more interesting options exist.

How does one describe a relation? The most common description is that of a subset of the product as in the example above, similar to the graph of a function. This is a set, so the usual suggestions for describing sets apply.

Quite often it is possible to describe a relation using a predicate.

**Example 0.31.** The relation which connects the integers  $m$  and  $n$  if  $m$  divides  $n$  is

$$\{(m, n) \in \mathbb{Z} \times \mathbb{Z} \mid n \text{ div } m = 0\}.$$

We may apply more complicated conditions to pick out the set of pairs we want to describe.

**Example 0.32.** The equality of fractions as rational numbers provides

<sup>37</sup>Note that this chapter is studied in Semester 2.

another example. This relation is defined as

$$\{(m/n, m'/n') \mid m, n, m', n' \in \mathbb{Z} \text{ and } mn' = m'n\}.$$

It is less often the case that one can use the idea of generating the relation as a set. This typically only works if there is a way of expressing one of the pair in terms of the other.

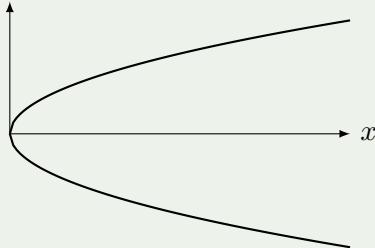

**Example 0.33.** The relation  $(r, r')$  in  $\mathbb{R}^2$  with  $r^2 = r'$  can be generated as

$$\{(r, r^2) \mid r \in \mathbb{R}\}.$$

Note that in this particular case it is also possible to describe the same relation as the union of two sets, namely as

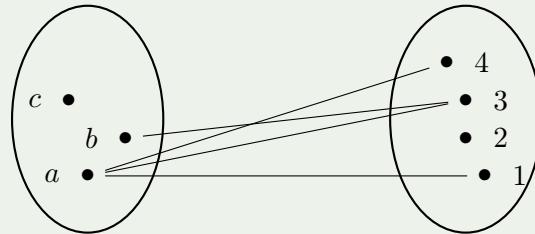

$$\{(\sqrt{r}, r) \in \mathbb{R} \times \mathbb{R} \mid r \in \mathbb{R}\} \cup \{(-\sqrt{r}, r) \in \mathbb{R} \times \mathbb{R} \mid r \in \mathbb{R}\}.$$

In a case like this it is easy to show a picture of the set in question.

If the relation is finite (and small) then it may be possible to list all the elements it contains. In this case it is also possible to draw a graph to indicate which elements are related.

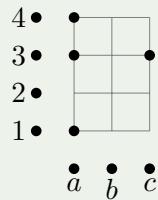

**Example 0.34.** Here is the kind of graph one might draw for a small relation.

This is the relation which relates  $a$  to 4, 3 and 1, it relates  $b$  to 2, and it relates  $c$  to nothing at all. Its set description is

$$\{(a, 1), (a, 3), (a, 4), (b, 2)\}.$$

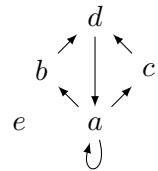

Alternatively one could draw those pairs in the product set that belong to the relation in this way, similar to the graph of a function (see Section 0.3.4):

You may think of the grid as giving all the possible combinations when picking one element from  $\{a, b, c\}$  and one from  $\{1, 2, 3, 4\}$ . The dot tells you whether the corresponding pair belongs to the relation, or not.

Note that every function defines a relation between its source and its target via its graph. These are very special relations, described in more detail in Section 7.1.

If we have a binary relation from one set to itself then we can picture this by drawing connections between the elements of the given set. Typically we would say that we have ‘a (binary) relation on the set  $S$ ’ instead of ‘a (binary) relation from  $S$  to  $S$ ’.

This is a picture of the following relation on the set  $\{a, b, c, d, e\}$ :

$$\{(a, a), (a, b), (a, c), (b, d), (c, d), (d, a)\}.$$

Note that relations do not have to be *binary*, they can have a higher arity. A ternary relation for sets  $S$ ,  $T$  and  $U$ , for example, is a subset of  $S \times T \times U$ . This kind of relation is difficult to picture in two dimensions, so typically no pictures are drawn for these.

# Chapter 1

# Complex Numbers

The real numbers allow us to solve many equations, but equations such as

$$x^2 = -1$$

have no solutions in  $\mathbb{R}$ .

One way of looking at the complex numbers is that they remedy this problem. But assuming this is all they do would sell them far short. We here give a short introduction to the set of complex numbers, addition and multiplication operations for them, and their basic properties.

Note that in order to solve exercises in this chapter you should only use properties given by Facts 1 to 7 in Chapter 0.

## 1.1 Basic definitions

We begin by giving some basic definitions.

### Definition 15

The set of complex numbers  $\mathbb{C}$  consists of numbers of the form

*réel*  $a + bi$  *imaginaire*

where  $a, b$  in  $\mathbb{R}$ . Here  $a$  is known as the **real part** and  $b$  as the **imaginary part** of the number.

At first sight it is not entirely clear what exactly we have just defined. One may view  $a + bi$  as an expression in a new language.

If one of  $a$  or  $b$  is 0 it is customary not to write it, so the complex number  $a$  is equal to  $a + 0i$  and the complex number  $bi$  is equal to  $0 + bi$ . Similarly, if  $b = 1$  then it is customary to write  $a + i$  instead of  $a + 1i$ .

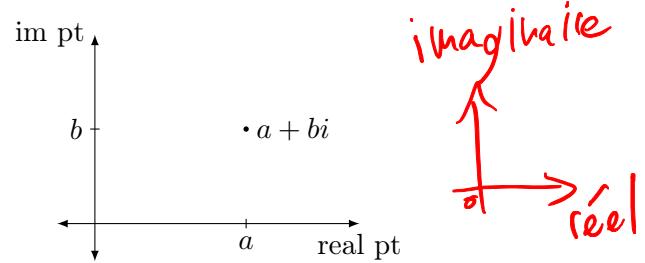

We may think<sup>1</sup> of a real number  $r$  as being a complex number whose imaginary part is 0, so it has the form  $r + 0i$ . In that way the complex numbers can be thought to include the real numbers (just as we like to think of the real numbers as including the rational numbers).

This gives a function from  $\mathbb{R}$  to  $\mathbb{C}$  defined by

$$r \longmapsto r + 0i.$$

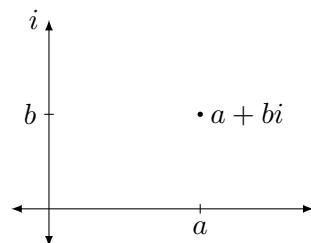

<sup>1</sup>Compare this with casting a value of one datatype to another in Java.

Complex numbers are usually drawn as points within the plane, using the horizontal axis for the real and the vertical axis for the imaginary part.

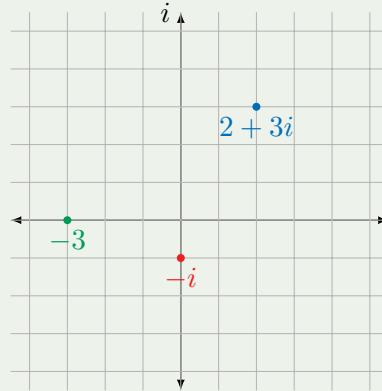

Above we have added labels for orientation, but usually this is done a bit differently.

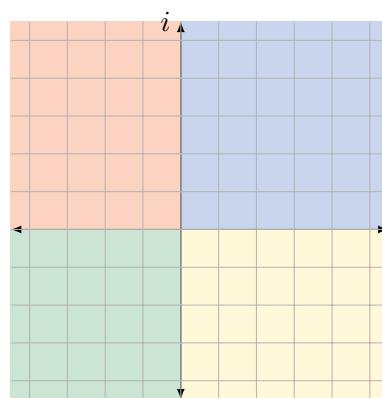

Instead of marking the real and the imaginary part on the axes it is more common to mark the ‘imaginary axis’ with  $i$ , giving a picture in the *complex plane*.

**Example 1.1.** We show how to draw the numbers  $2 + 3i$ ,  $-3$  and  $-i$  in the complex plane.

The complex plane is naturally divided into four quadrants.

## 1.2 Operations

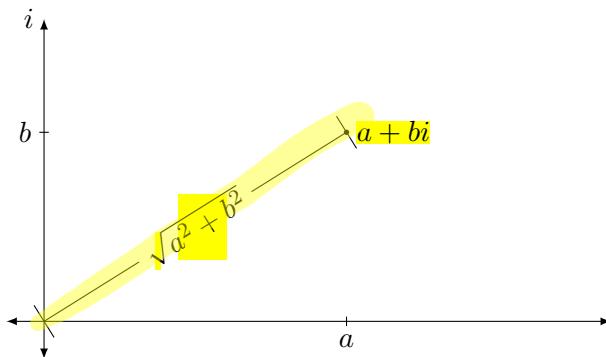

There are quite a few operations one defines for complex numbers.

### 1.2.1 The absolute

The<sup>2</sup> absolute  $|a + bi|$  of a complex number  $a + bi$  is given by

$\sqrt{a^2 + b^2}$  module / absolute

We may think of this as the length of the line that connects the point 0 with the point  $a + bi$ :

**Example 1.2.** The absolute of the complex number  $1 + 2i$  is calculated as follows.

$$|1 + 2i| = \sqrt{1^2 + 2^2} = \sqrt{5}.$$

Note that this extends the notion of absolute for real numbers in the sense that

$$|a + 0| = \sqrt{a^2 + 0} = \sqrt{a^2} = |a|$$

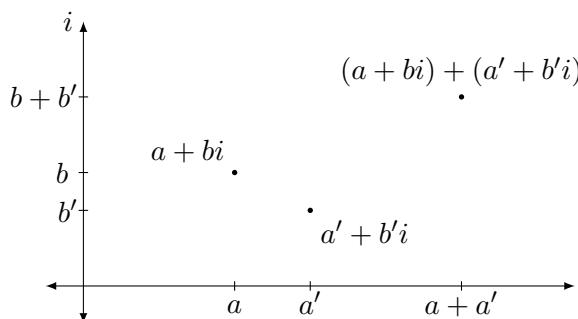

where we use the absolute function for real numbers on the right.<sup>3</sup>

One can calculate with the complex numbers based on the following operations.

### 1.2.2 Addition

We set

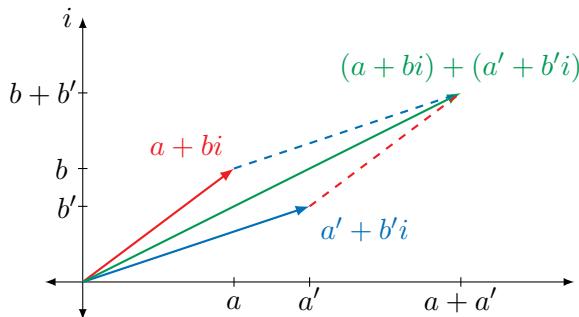

$$\begin{aligned} (a + bi) + (a' + b'i) &= (a + a') + (b + b')i. \end{aligned}$$

<sup>2</sup>This is also known as the *modulus* of a complex number.

<sup>3</sup>And indeed note that we could use  $\sqrt{r^2}$  as a definition of the absolute for a real number  $r$ .

To understand addition it is useful to think of the numbers in the complex plane as<sup>4</sup> *vectors*, then addition is just the same as the addition of vectors:

If you prefer, you may think of this as taking the vector for  $a' + b'i$  and shifting it so that its origin coincides with the end point of the vector for  $a + bi$ .<sup>5</sup>

**Example 1.3.** We calculate the sum of  $1 + 2i$  and  $-1 + i$  as follows.

$$(1 + 2i) + (-1 + i) = (1 - 1) + (2 + 1)i = 3i.$$

We note that if we have two complex numbers whose imaginary part is 0, say  $a$  and  $a'$ , then their sum as complex numbers is  $a + a'$ , that is their sum as real numbers.

Important properties of this operation are established in Exercise 25 and 26, which establish two equalities from Fact 6 for the complex numbers.

Note that 0 is the unit for addition<sup>6</sup>, that is adding 0 to a complex number (on either side) has no effect.<sup>7</sup> In other words we have

$$\begin{aligned} 0 + (a + bi) &= (0 + a) + (0 + b)i && \text{def addition} \\ &= a + bi && \text{addition for reals} \\ &= (a + 0) + (b + 0)i && \text{addition for reals} \\ &= (a + bi) + 0. && \text{def addition} \end{aligned}$$

$(a+0i)+(a'0i)$   
 ||  
 $a+a'$

For the real numbers every element  $r$  has an *inverse* for addition in the form of  $-r$ : This is the unique number<sup>8</sup> which,<sup>9</sup> if added to  $r$  on either side, gives the unit for addition 0.

For addition of complex numbers we can find an inverse by making use of the inverse for addition for the reals. The following lemma explains how to calculate the additive inverse, and it also establishes that such an inverse exists for all complex numbers.

<sup>4</sup>Vectors will be taught in detail in the second half of Semester 2.

<sup>5</sup>Note that you may just as well think of shifting the vector for  $a + bi$  such that its origin coincides with the end point of the vector for  $a' + b'i$ .

<sup>6</sup>Look at the unit for addition given by Facts 1, 3, 5 and 6.

<sup>7</sup>For a formal definition of the unit of an operation see 19.

<sup>8</sup>Again, compare Facts 3, 5 and 6 from the previous chapter.

<sup>9</sup>For a formal definition of the inverse for a given element with respect to a given operation see 20 in the following chapter.

**Lemma 1.1**

The additive inverse of the complex number  $a + bi$  is

$$-(a + bi) = -a + (-b)i = -a - bi.$$

This establishes that every element of  $\mathbb{C}$  has an additive inverse and that means we may define *subtraction for complex numbers* by setting

$$(a + bi) - (a' + b'i) = (a + bi) + - (a' + b'i),$$

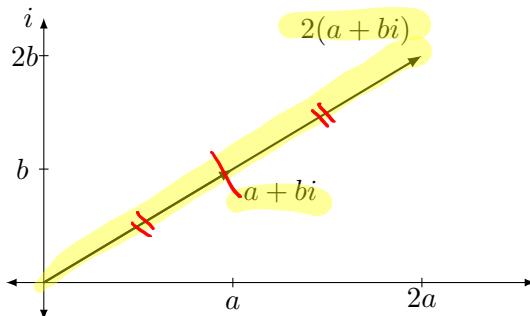

so as usual this is a shortcut to deducting the additive inverse of the second argument from the first argument.

**Exercise 11.** Prove Lemma 1.1. Hint: The paragraph above this exercise tells you what you need to check, or look ahead to Definition 20.

Note that there is no easy connection between the absolute and addition; the best we may establish for complex numbers  $z$  and  $z'$  is that

$$|z + z'| \leq |z| + |z'|.$$

Note that  $(a + bi) + (a + bi) = 2a + 2bi$ , and that we may think of this as stretching  $a + bi$  to twice its original length, and write it as  $2(a + bi)$ :

In general, given a real number  $r$  and a complex number  $a + bi$  we may define

$$r(a + bi) = ra + rbi.$$

**Example 1.4.** We see that  $3(5 + i) = 15 + 3i$ , and we further calculate  $-\sqrt{2}(\sqrt{2} - \sqrt{2}i) = 2 - 2i$ .

**Exercise 12.** Draw the following numbers in the complex plane:  $2 - 2i$ ,  $2i$ ,  $-2i$ ,  $3 + i$ ,  $-(3 + 4i)$ ,  $(-1 + 2i) + (3 + i)$ ,  $(1 + 2i) + (3 - i)$ ,  $(1 + 2i) - (3 + i)$ . For each quadrant of the complex plane pick one of these numbers (you may pick at most two numbers lying on an axis, and the axes have to be on different ones), and calculate its absolute.

Assume you are given a complex number  $z$ , and that you have drawn it on the complex plane. From that situation describe in general how to draw the following.

(a)  $-z$ ,

- (b)  $2z$ ,  
(c)  $3z$ ,  
(d)  $rz$ , where  $r$  is an arbitrary real number.

**Exercise 13.** Consider the function  $f$  from  $\mathbb{R}^2$  to  $\mathbb{C}$  which is defined as follows:

$$(a, b) \longmapsto a + bi.$$

Show that  $f(a, b) + f(a', b') = f((a, b) + (a', b'))$  for all  $(a, b), (a', b') \in \mathbb{R}^2$ .

### 1.2.3 Multiplication

We define the multiplication operation on complex numbers by setting

$$(a + bi)(a' + b'i) = aa' - bb' + (ab' + ba')i.$$

**Example 1.5.** We calculate

$$(1 + 2i)(2 - 3i) = (2 + 6) + (4 - 3)i = 8 + i.$$

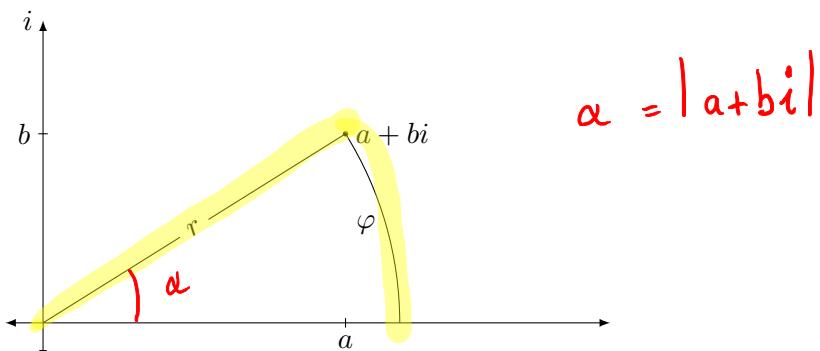

**Exercise 14.** Show that 1 is the unit for multiplication. Hint: Check the calculation carried out above which shows that 0 is the unit for addition. Also look at Fact 1 which tells you what it means for 1 to be the unit for multiplication of natural numbers.

Note that if one of the numbers has imaginary part 0 then we retain the multiplication with a real number defined above, that is

$$a(a' + b'i) = aa' + ab'i.$$

There is a geometric interpretation of multiplication, but it is a bit more complicated than that for addition. We here only give a sketch of this.

Instead of giving the coordinates  $a$  and  $b$  to describe a point in the complex plane one also could give an angle and a length—this is known as describing a number using polar coordinates.

This angle is often called the argument of the complex number, and the length  $r$  is nothing but the absolute value  $|a + bi|$  from above.

**Example 1.6.** The complex number  $1+i$  has the absolute  $\sqrt{2}$  and the argument  $45^\circ$  or, if you prefer,  $\pi/4$ .

This means there are two ways of describing a complex number:  
via  $a+bi$  through missing?

- the real part  $a$  and
- the imaginary part  $b$
- the absolute  $r$  and
- the argument  $\varphi$ .

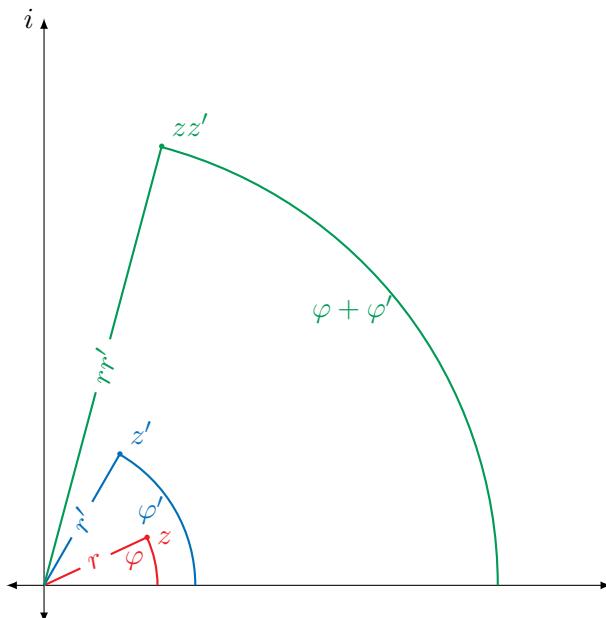

To move from polar coordinates to the standard form there is a simple formula: The complex number given by  $r$  and  $\varphi$  is

$$r(\cos \varphi + (\sin \varphi)i).$$

In the other direction one can use the arctangent function  $\arctan$ , the partial inverse of the tangent function, to calculate  $\varphi$  given  $a$  and  $b$ , but a few case distinctions are required.

**Optional Exercise 4.** Write out the definition of the function that gives the argument, for a complex number  $a+bi$ . Then prove that, starting from a complex number, calculating the angle and the absolute, and then calculating the real and imaginary part from the result, gives back the number one started with. Use these calculations to show that the argument of  $zz'$  is the argument of  $z$  plus the argument of  $z'$ .

Describing multiplication is much easier when we do it with respect to these polar coordinates: the product of numbers  $z$  and  $z'$  given by  $\varphi$  and  $r$  and  $\varphi'$  and  $r'$  respectively has the absolute  $rr'$  and the argument  $\varphi + \varphi'$ .

Note that there is a nice connection between the absolute and multiplication

### Lemma 1.2

For complex number  $z$  and  $z'$  we have

$$|zz'| = |z||z'|.$$

### Exercise 15.

Prove Lemma 1.2.

We note that according to the definition of multiplication we have

$$ii = (0 + 1i)(0 + 1i) = 0 - 1 \cdot 1 + (0 \cdot 1 + 1 \cdot 0)i = -1,$$

so in the complex numbers we may solve the equation

$$x^2 = -1$$

which has no solution in  $\mathbb{R}$ .

**CExercise 16.** Pick four numbers in at least three different quadrants of the complex plane. Calculate, and then draw, their product with the number  $i$ . Describe in general where to draw  $iz$  given the position of  $z$ .

**Optional Exercise 5.** What happens if we keep multiplying  $i$  with itself? What does that tell you about solutions to the equation  $x^4 = 1$ ? What about solutions for  $x^n = 1$  more generally?

**Exercise 17.** Consider the function  $f$  from  $\mathbb{R}^2$  to  $\mathbb{C}$  which is defined as follows:

$$(a, b) \longmapsto a + bi.$$

Define addition and multiplication on  $\mathbb{R}^2$  based on these operations for complex numbers. Hint: You may want to consult Exercise 13.

We have seen that with regards to addition, every complex number  $z$  has an inverse in the form of  $-z$ . What about inverses for multiplication?

### Lemma 1.3

For every complex number  $a + bi \neq 0$  the multiplicative inverse is given by<sup>10</sup>

$$\frac{a}{a^2 + b^2} - \frac{b}{a^2 + b^2}i.$$

Sometimes the notation

$$(a + bi)^{-1}$$

is used for this number. More generally, if we have a complex number  $z$  then its inverse, if it exists, is written as  $z^{-1}$ . Just as for real numbers the expression

$$z/z'$$

is a shortcut for

$$z(z')^{-1}.$$

<sup>10</sup>Note that our condition means that  $a^2 + b^2 \neq 0$  and therefore we may form the fractions given here.

**Do not divide by complex numbers in your work.** The correct operation is to multiply with the multiplicative inverse, and for full marks you have to include an argument that this exists in the case you are concerned with.

Whenever you use the number  $z^{-1}$  you have to include an argument that this exists, that is, that  $z \neq 0$  (and indeed you should do this whenever you use  $r^{-1}$  for real or rational numbers).

Recall that we avoid talking about division as an operation on this unit, so if you want to remove a factor from an equation please try to talk about multiplying with the multiplicative inverse, and think about whether this exists!

**EExercise 18.** Prove Lemma 1.3 Hint: Check Fact 5 from the previous chapter to see what you have to prove, or look ahead to Definition 20.

Calculate the inverse of the complex number  $a = a + 0i$ . How does that compare with the inverse for  $a$  when viewed as an element of  $\mathbb{R}$ ? Example

**EExercise 19.** Assume you are given the absolute and argument of a complex number. What are the absolute and argument of the multiplicative inverse of that number? Hint: What does multiplication with the inverse have to give? Look at the picture on page 59 which explains multiplication in terms of absolute and argument to find a number that satisfies the requirement for an arbitrary absolute  $r$  and argument  $\varphi$ .

In summary we have seen that just as for the real numbers, we may define addition and composition for complex numbers, and in such a way that if we treat real numbers as particular complex ones, then the operations agree. Indeed, it is also possible to define exponentiation and logarithms for complex numbers but this idea leads us too far afield.

#### 1.2.4 Conjugation

There is a further operation that you may find in texts that deal with complex numbers, namely **conjugation**. The conjugate  $\bar{z}$  of a complex number  $z = a + bi$  is given by  $a - bi$ .

**Example 1.7.** We give sample calculations.

$$\overline{-2+i} = -2-i, \quad \bar{3} = 3, \quad \bar{i} = -i.$$

**Exercise 20.** Assume you have a complex number given by its absolute and argument. What are the absolute and argument of its conjugate? Hint: If you find this difficult draw a few examples in the complex plane.

**CExercise 21.** Show that  $z\bar{z} = |z|^2$ .

## 1.3 Properties

The complex numbers have various properties which make them a nice collection of numbers to work with. You are allowed to use the following in subsequent exercises on complex numbers.<sup>11</sup>

### Fact 8

Addition and multiplication of the complex numbers have all the properties of the real numbers as given in Fact 6.

**Optional Exercise 6.** Prove the statements of Fact 8.

Note that when it comes to solving equations, the complex numbers are even better behaved than the real ones: Every polynomial equation, that is an equation of the form

$$\sum_{i=0}^n c_i x^i = c_n x^n + c_{n-1} x^{n-1} + \cdots + c_1 x + c_0 = 0,$$

where the  $c_i$  are complex numbers has at least one solution<sup>12</sup> in  $\mathbb{C}$ , whereas this is not true in  $\mathbb{R}$  even if the  $c_i$  are all elements of  $\mathbb{R}$ . This means that the complex numbers are particularly suitable for various constructions that depend on having solutions to polynomials.

Note that it does not make any sense to use the square root operation for complex numbers. While for a positive number  $r$ , we use the symbol

$$\sqrt{r}$$

to refer to the positive of the two solutions to the equation

$$x^2 = r$$

for a complex number  $z$  there is no sensible way of picking out one of the possible solutions of

$$x^2 = z.$$

**Example 1.8.** Consider the equation

$$x^2 = i.$$

We may check that there are two solutions,

$$\frac{1}{\sqrt{2}}(1+i) \quad \text{and} \quad \frac{1}{\sqrt{2}}(-1-i).$$

Which of those should be the number we mean by  $\sqrt{i}$ ? You may think there's still a sensible choice, namely the one where both, real and imaginary part are positive.

<sup>11</sup>You are not allowed to use them in exercises where you are specifically asked to prove them!

<sup>12</sup>In fact, one can show that there are  $n$  solutions, but this requires counting some solutions more than once.

Now consider the equation

$$x^2 = -i.$$

It has the solutions

$$\frac{1}{\sqrt{2}}(-1 + i) \quad \text{and} \quad \frac{1}{\sqrt{2}}(1 - i),$$

and picking one over the other does not make sense.

If we go to equations involving powers higher than two then the number of solutions increases.

**Example 1.9.** Let us consider the following equation:

$$x^4 = 1.$$

If  $x$  is supposed to be a real number then there are two solutions, namely 1 and  $-1$ .

If, on the other hand, we are allowed to pick solutions from  $\mathbb{C}$  we note that there are at least four:

$$1, \quad -1, \quad i, \quad -i.$$

Certainly there is no good way of picking out one of these solutions to determine which number we might mean by  $\sqrt[4]{1}$ .

For this reason there are no root operations on the complex numbers.

Do not use square root symbols if you are interested in a solution of the equation  $z^2 = z'$ , where  $z'$  is given. This is not a valid operation for complex numbers.

An important difference between the complex numbers and the other sets of numbers discussed in Chapter 0 is that we are used to thinking of the latter as being *ordered*, which means we can compare two elements. There is no way of turning  $\mathbb{C}$  into an ordered set so that the statements in Fact 7 are true for that order.

In analysis, which includes the study of functions, their derivatives and their integrals, the theory of functions of complex numbers is much smoother than its counterpart for the reals. In order to calculate various (improper) integrals for functions of real variables one may apply methods that require functions of complex variables.

The fact that complex numbers may be thought of as having two parts, and that we have various operations for these, means they are particularly suited to a number of application areas where these operations may be interpreted.

## 1.4 Applications

Complex numbers may appear artificial, and having numbers with an ‘imaginary’ part may suggest that these are merely figments of some mathemati-

cians' imagination.

It turns out, however, that they are not merely some artefact whose only use it is to deliver a number which is a square root of  $-1$ . Because complex numbers can effectively be thought of as vectors, but vectors which allow multiplication as well as addition, they are very useful when it comes to talking about quantities that need a more complex structure to express them than just one number.

In physics and various areas of engineering quantities which may be described by just one number are known as 'scalars'. Examples are distance, speed (although to describe movement one might want to include direction with speed) and energy. In a direct-current circuit, voltage, resistance and current are treated as scalars without problem. In alternating current circuits, however, there are notions of frequency and phase shift which have to be taken into account, and it turns out that using complex numbers to describe such circuits results in a very useful depiction. Moreover some calculations become much simpler when one exploits the possibilities given by modelling the circuit with complex numbers.

Signal analysis is another area where complex numbers are often employed. Again the issue here are periodically varying quantities. Instead of describing these using a sine or cosine function of some real variable, employing the extensions of these functions to the complex numbers makes it possible to describe the amplitude and phase at the same time. In the second year course on Mobile Systems, COMP28512, these ideas are used.

There you will see for example, that by using complex numbers for a Fourier transform calculations that look complicated can be carried out via matrix multiplication.<sup>13</sup> When you meet this material you should remind yourself of what you know about complex numbers from these notes.

There are other areas where applications arise, such as fluid dynamics, control theory and quantum mechanics.

---

<sup>13</sup>The latter will be treated towards the end of Semester 2 of this course unit.

## Chapter 2

# Statements and Proofs

Mathematics is a discipline that relies on rigorous definitions and formal proofs. As a consequence, in mathematics statements hold, or they do not (but we may not know which it is).<sup>1</sup> This is very different from the situation in the natural sciences, for example. Here a theory may be falsified by observations that contradict it, but there is no way of formally verifying it.

How does a system that seeks to provide such certainty work? In principle the thought is that it is possible to define a theory strictly from first principles (typically starting with a formal theory of sets), with rules for deriving statements from existing ones. Such a system is very rigid and syntactic<sup>2</sup> in nature, much like a computer language (and indeed there are computer programs that implement at least aspects of this). Statements that may be formally derived in the system are known as theorems. In principle it should be possible to fit all of mathematics into a formal system like this.<sup>3</sup>

But in practice this is not what mathematicians do. There are two reasons for this. Starting from first principles it takes a very long time to build up the apparatus required to get to where one may even talk about entities such as the real numbers with complete rigour. Secondly the resulting statements are very unwieldy and not human-readable. Hence mathematicians carry out their work in some kind of *meta-language* which in principle can be translated into a formal system. Increasingly there are computer-verified proofs in some formal system in various areas, in particular in theoretical computer science.

In this and the following chapter of the notes we look at both these ideas—proofs as they are customarily carried out by mathematicians and a formal system.

---

<sup>1</sup>There are also issues to do with whether a given formal system allows us to construct a proof or a counterexample.

<sup>2</sup>This means concerned with symbols put together according to some rules without any concern what they might mean.

<sup>3</sup>But there is a famous result by the logician Kurt Gödel, his *Incompleteness Theorem*, which tells us that any system sufficiently powerful for most of mathematics cannot prove its own consistency.

## 2.1 Motivation

You are here to study computer science rather than mathematics, so why should you worry about proving statements? There are two reasons one might give here.

For one there is the area of *theoretical computer science* which arguably is also an area in mathematics. The aim of this part of computer science is to make formal statements and to prove them. Here are some examples of the kind of statement that are of concern in this area.

- This abstract computational device has the same computational power as another.
- This computation is equivalent to another.<sup>4</sup>
- This abstract computational system behaves in a particular manner over time.
- This problem cannot be solved by a computer, or, equivalently, there is no algorithm (or decision procedure) for it (see COMP11212).
- The best possible algorithm for this problem requires a number of steps that is a quadratic function in the size of the problem (see COMP26120).
- This program will terminate and after it has done so its result will satisfy a particular condition.
- This circuit implements a particular specification.

You can see that while the first few statements sound fairly abstract the latter two look as if they might be closer to real-world applications.

Secondly, under certain circumstances it is important to make absolute statements about the behaviour of a computational device (a chip or a computer program for example). Formally proving that programs behave in a particular way is labour-intensive (and creating a formal model of the real world in which the device lives is potentially error-prone).

In safety-critical systems, however, the benefits are usually thought to outweigh the cost. For example in an aircraft it is vital that the on-board computer behaves in a particular way. Emergency course corrections have to be made promptly and correctly or the result may be fatal for those on board. When NASA sends an explorer onto Mars, or the Voyager space craft to fly through the solar system (and to eventually leave it) then it is vital that a number of computer-controlled manoeuvres are correctly implemented. Losing such a craft, or rendering it incapable of sending back the desired data, costs large amounts of money and results in a major setback.

But even outside such applications computing is full of statements that are at least in part mathematical. Here are some examples.

- The worst case complexity of this algorithm is  $n \log n$  (the kind of statement that you will see in COMP26120).

---

<sup>4</sup>What it might mean for two computations to be equivalent is a whole branch of theoretical computer science.

- This recursive procedure leads to exponential blow-up.
- A simple classification rule is to choose the class with the highest posterior probability (from COMP14112).
- Time-domain samples can be converted to frequency domain using Fourier Transforms, which are a standard way of representing complex signal  $g(t)$  as a linear sum of basic functions  $f_g(t)$  (from COMP28512).

The aim of this course unit is to prepare you for both these: studying areas of theoretical computer science and making sense of mathematical statements that appear in other parts of the field.

## 2.2 Precision

Something the language of mathematics gives us is precision. You need to become familiar with some aspects of this. In particular, there are some key phrases which sound as if they might be parts of every-day language, which have a precise meaning in a mathematical context.

### 2.2.1 Key phrases

Vocabulary that helps us with this are phrases such as

- ‘and’,
- ‘or’,
- ‘implies’ (and the related ‘if and only if’),
- ‘there exists’ and
- ‘for all’.

The aim of this section is to introduce you to what these phrases mean, and how that is reflected by proving statements involving them.

#### Keyword And

Formally we use this word to connect several statements, or properties, and we demand that all of them hold.

When you enter several words into the Google search box you ask it to return pages which contain *all* the listed words—you are demanding pages that contain *word 1* and *word 2* and ...

If you are running database queries you are often interested in all entries that combine several characteristics, for example, you might want all your customers from a particular country for whom you have an email address so that you can make a special offer to them.

These are all informal usages, but they have fundamentally the same meaning as more mathematical ones.

**Example 2.1.** A very simple example is the definition of the intersection of two subsets  $S$  and  $T$  of a set  $X$ .

$$S \cap T = \{x \in X \mid x \in S \text{ and } x \in T\}.$$

In order to prove that an element  $x$  is in this intersection we have to prove both, that

$x$  is in  $S$  and that  $s$  is in  $T$ .

It is a good idea to structure proofs so that it is clear that these steps are carried out. Here is an example of this idea.

**Example 2.2.** To show that 6 is an element of

$$\begin{aligned} & \{n \in \mathbb{N} \mid n \bmod 2 = 0 \text{ and } n \bmod 3 = 0\} \\ &= \{n \in \mathbb{N} \mid n \bmod 2 = 0\} \cap \{n \in \mathbb{N} \mid n \bmod 3 = 0\} \end{aligned}$$

one splits the requirement into the two parts connected by *and*.

- To show that 6 is in the first set we have to show that  $6 \bmod 2 = 0$ , and we may conclude this from

$$6 = 3 \cdot 2 + 0,$$

Fact 2 and the definition of mod.

- To show that 6 is in the second set we have to show  $6 \bmod 3 = 0$ , and we may conclude this in the same way from  $6 = 2 \cdot 3 + 0$ .

Overall this means that 6 is in the intersection as required.

This usage of ‘and’ may also be observed in every-day language: If I state ‘it is cloudy and it is raining’ then I am claiming that both of the following statements are true:

It is cloudy.

It is raining.

**Example 2.3.** In order to check that a first year student in the School satisfies the degree requirement, and is enrolled on COMP10120 as well as being enrolled on COMP16120 I have to do both,

- check that the student is enrolled on COMP10120 and
- check that the student is enrolled on COMP16120.

**Example 2.4.** In order to establish

it is sufficient to show one of  $x \notin S \cap T$

*pas besoin de prouver les deux*

$x \notin S$	$x \notin T$
--------------	--------------

In general, in order to argue that a statement of the form (Clause 1 and Clause 2) does not hold it is sufficient to show that one of the two clauses fails to hold.

**Example 2.5.** In order to argue that it is not the case that

3 is a prime number and 3 is even

it is sufficient to be able to state that since 3 leaves the remainder of 1 when divided by 2 it is not even by Definition 4.

### Keyword Or

We connect two statements or properties with ‘or’ if at least one (but possibly both of them) hold.

To use the Google search box as an example once again, if you type two entries separated by ‘OR’ it will look for pages which contain one of the two words.

This is also a fairly standard database query: You might be interested in all the customers for whom you have a landline or a mobile phone number, or all the ones who have ordered product  $X$  or product  $Y$  because you have an accessory to offer to them.

**Example 2.6.** Again a simple example is given by sets, namely by the definition of the union of two subsets  $S$  and  $T$  of a set  $X$ , which is given by

$$\{x \in X \mid x \in S \text{ or } x \in T\}.$$

For a concrete version of this see the following example.

**Example 2.7.** In order to show that 6 is an element of

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0 \text{ or } n \bmod 3 = 0\}$$

it is sufficient to prove *one* of the two parts. It is therefore sufficient to state that

- Since  $6 = 3 \cdot 2 + 0$  we have that  $6 \bmod 2 = 0$  by the definition of mod.

It is not necessary to check the other clause.

en peut  
en prouver  
un seul et  
c'est  
suffisant

This suggests a proof strategy: Look at both cases separately, and stop when one of them has been established.

Again this usage is well established in informal language (although usage tends to be less strict than with ‘and’). If I say ‘Tomorrow I will go for a walk or a bicycle ride’ then I expect (at least) one of the following two sentences to be true:

Tomorrow I will go for a walk.

Tomorrow I will go for a bicycle ride.

There is no information regarding which one will occur—and indeed I may find the time to do both!

pour prouver 'or' = 1 des 2 conditions doit être valide

pour argumenter 'or' = les 2 conditions doivent être prouvées

**Example 2.8.** If the degree rules state that a student on the Computer Science with Business and Management programme must take one of COMP11212 and COMP14112 then I can stop checking once I have seen that the student is enrolled on COMP11212.

Note that in informal language 'or' often connects incompatible statements, which means that at most one of them is true. This is never the meaning in mathematics. If we wanted to express this we would have to say 'Exactly one of Statement 1 and Statement 2 holds'.

In order to show that a statement of the form (Clause 1 or Clause 2) does not hold we have to show that neither of the clauses holds.

**Example 2.9.** In order to show that

$$x \notin S \cup T$$

we have to establish both.

$$x \notin S \quad \text{and} \quad x \notin T,$$

**Example 2.10.** In order to show that 7 is not an element of

$$\{n \in \mathbb{N} \mid n \bmod 2 = 0 \text{ or } n \bmod 3 = 0\}$$

I have to argue in two parts:

- Since  $7 \bmod 2 = 1 \neq 0$  we see that 7 does not satisfy the first condition.
- Since  $7 \bmod 3 = 1 \neq 0$  we see that 7 does not satisfy the second condition.

Hence 7 is not in the union of the two sets.

### Keyword Implies

This is a phrase that tells us that if the first statement holds then so does the second (but if the first statement fails to hold we cannot infer anything about the second).

For this notion it is harder to find examples outside of mathematics, but you might want to ensure that in your database, the existence of an address entry for a customer implies the existence of a post code.

Again a simple formal example can be found by looking at sets.

**Example 2.11.** If  $S$  and  $T$  are subsets of some set  $X$  then

$$S \subseteq T$$

means that given  $x \in X$ ,

$$x \in S \quad \text{implies} \quad x \in T.$$

In order to establish that  $S \subseteq T$  given  $x \in X$  one only has to show something in case that  $x \in S$ , so usually proofs of that kind are given by assuming that  $x \in S$ , and then establishing that  $x \in T$  also holds. We look at a concrete version of this.

**Example 2.12.** To show, that

$$\{n \in \mathbb{N} \mid n \bmod 6 = 0\} \subseteq \{n \in \mathbb{N} \mid n \bmod 3 = 0\}$$

we pick an arbitrary element  $n$  in the former set. Then  $n \bmod 6 = 0$ , and by the definition of mod this means that there is

$$k \in \mathbb{N} \quad \text{with} \quad n = k6 + 0.$$

But that means that

$$n = k6 = k(2 \cdot 3) = (k2)3$$

using Fact 1, and so picking  $l = 2k$  we can see that  $n = 3l + 0$ , which means that  $n \bmod 3 = 0$ .

Typically we do not use ‘implies’ in informal language, but we have constructions that have a similar meaning. I might state, for example, ‘if it rains I will stay at home’. So if on the day it is raining you should not expect to meet me, you should expect me to be at home. Note that this does not allow you to draw any conclusions in the case where it is not raining, although many people tend to do so. (‘But you said you wouldn’t be coming only if it was raining ...’.) If I say ‘if it is raining I will definitely stay at home’ I’ve made it clearer that I reserve the right to stay at home even if it is not raining. Note that in the formal usage of ‘implies’ the meaning is completely precise.

**Example 2.13.** One might use implication to state that if a student is in a tutorial group  $W_n$ , where  $n$  is a natural number, then the student is in lab group  $W$ .

In order to show that this is true one has to check all the tutorial groups that start with  $W$  and make sure<sup>5</sup> their members are in lab-group  $W$ .

In order to show that a claimed implication does not hold one has to find an instance where the first clause holds while the second does not. So in order to catch me out as having said an untruth in the above example, you’ve got to find me out of the house when it is raining at the appointed time.

**Example 2.14.** In order to refute the claim that, for a natural number  $n$ ,

$$n \text{ divisible by } 2 \quad \text{implies} \quad n \text{ divisible by } 6$$

<sup>5</sup>But this is the definition of labgroup  $W$  so we don’t actually have to check this in reality!

pour prouver que ‘implies’ ne marche pas, il faut confondre l’argument

we need to find a number that

- fulfills the first part, that is, it must be divisible by 2, but
- does not fulfill the second part, that is, is not divisible by 6.

Since  $4 = 2 \cdot 2$  the number 4 is divisible by 2 according to Definition 3. Since there is no number  $k \in \mathbb{N}$  with  $4 = 6k$ , the number 4 is not divisible by 6, which establishes that the claimed implication is false.

### Key phrase If and only if

This phrase is merely a short-cut. When we say that

$$\text{Statement 1 (holds)} \quad \text{if and only if} \quad \text{Statement 2 (holds)}$$

then we mean by this that both,

$$\text{Statement 1} \quad \text{implies} \quad \text{Statement 2}$$

and

$$\text{Statement 2} \quad \text{implies} \quad \text{Statement 1}.$$

To prove for two sets  $S, T \subseteq X$  that

$$S = T$$

is equivalent to showing that for all  $x \in X$ , we have

$$x \in S \quad \text{if and only if} \quad x \in T,$$

which is equivalent to showing that

$$S \subseteq T \quad \text{and} \quad T \subseteq S.$$

**Example 2.15.** To show that

$$S = \{n \in \mathbb{N} \mid n \bmod 6 = 0\}$$

is equal to

$$T = \{n \in \mathbb{N} \mid n \bmod 2 = 0\} \cap \{n \in \mathbb{N} \mid n \bmod 3 = 0\}$$

we show that  $S \subseteq T$  and that  $T \subseteq S$ .

It is a good idea to optically structure the proof accordingly.

$S \subseteq T$ . Given  $n \in S$  we know that  $n \bmod 6 = 0$  which means that we can find  $k \in \mathbb{N}$  with  $n = k6$ . This means that both

- $n = (k3)2$  and so  $n \bmod 2 = 0$  and
- $n = (k2)3$  and so  $n \bmod 3 = 0$

and so  $n \in T$ .

$T \subseteq S$ . Given  $n \in T$  we know that both

- $n \bmod 2 = 0$ , which means that there is  $k \in \mathbb{N}$  with  $n = k2$  and

- $n \bmod 3 = 0$ , which means that there is  $l \in \mathbb{N}$  with  $n = l3$ .

This means that 2, which is a prime number, divides  $n = l3$ . By Definition 16 this means that

- 2 divides 3 (which clearly does not hold) or
- 2 divides  $l$ , which means that there exists  $j \in \mathbb{N}$  with  $l = j2$ .

Altogether this means that  $n = l3 = j2 \cdot 3 = j6$ , and so  $n$  is divisible by 6.

Quite often when proving an ‘if and only if’ statement the best strategy is to prove the two directions separately. The only exception is when one can find steps that turn one side into the other, and every single step is reversible.

In order to show that an if and only if statement does not hold it is sufficient to establish that one of the two implications fails to hold.

### Key phrase For all

Again a phrase that is very common in mathematical definitions or arguments, but there are other uses. For example you might want to ensure that you have an email address for every customer in your database.

**Example 2.16.** Consider the following statement.

for all elements  $k$  of  $\{4n \mid n \in \mathbb{N}\}$  we have that  $k$  is divisible by 2.

In order to show that this is true I have to assume that I have an arbitrary element  $k$  of the given set. In order for  $k$  to be in that set it must be the case that there exists  $n \in \mathbb{N}$  such that  $k = 4n$ . But now

$$k = 4n = 2(2n)$$

and according to Definition 3 this means that  $k$  is divisible by 2.

Since an arbitrary element of the given set satisfies the given condition, they must all satisfy it.

A ‘for all’ statement should have two parts.

- For which elements are making the claim? There should be a set associated with this part of the statement (this is  $\mathbb{N}$  in the previous example).
- What property or properties do these elements have to satisfy? There should be a statement which specifies this. In the previous example it is the statement that the number is divisible by 2.

Typically when proving a statement beginning with ‘for all’ one assumes that one has an unspecified element of the given set, and then establishes the desired property.

**Example 2.17.** Looking back above at the statement that one set is the subset of another, we have, strictly speaking, suppressed a ‘for all’ statement.

Given subsets  $S$  and  $T$  of a set  $X$  the statement

$$S \subseteq T$$

is equivalent to

$$\boxed{\text{for all } x \in X \quad x \in S \text{ implies } x \in T.}$$

In the proof in Example 2.12 we did indeed pick an arbitrary element of the first set, and then showed that it is an element of the second set.

**Example 2.18.** A nice example of a ‘for all’ statement is that of the equality of two functions with the same source and target. Let  $f: S \rightarrow T$  and  $g: S \rightarrow T$  be two functions. Then

$$f = g$$

if and only if

$$\text{for all } s \in S \text{ we have } fs = gs.$$

We look at a concrete version of this idea.

**Example 2.19.** Consider the following two functions.

$$\begin{array}{ccc} f: \mathbb{N} & \xrightarrow{\hspace{2cm}} & \mathbb{N} \\ n & \longmapsto & 2(n \text{ div } 2) \end{array} \qquad \begin{array}{ccc} g: \mathbb{N} & \xrightarrow{\hspace{2cm}} & \mathbb{N} \\ n & \longmapsto & \begin{cases} n & n \text{ is even} \\ n - 1 & \text{else.} \end{cases} \end{array}$$

To show that the two functions are equal, assume we have an arbitrary element  $n$  of the source set  $\mathbb{N}$ . The second function is given in a definition by cases, and usually it is easier to also split the proof into these two cases.

- Assume that  $n$  is even, which means that  $n \text{ div } 2 = 0$  by Definition 4. In this case

$$\begin{aligned} fn &= 2(n \text{ div } 2) && \text{def } f \\ &= 2(n \text{ div } 2) + 0 && 0 \text{ unit for addition} \\ &= 2(n \text{ div } 2) + n \bmod 2 && n \text{ even} \\ &= n && \text{Lemma 0.1} \\ &= gn && \text{def } g. \end{aligned}$$

- Assume that  $n$  is not even, which means that  $n \text{ div } 2 = 1$  by Defi-

nition 4. In this case

$$\begin{aligned}
 fn &= 2(n \text{ div } 2) && \text{def } f \\
 &= 2(n \text{ div } 2) + 0 && 0 \text{ unit for addition} \\
 &= 2(n \text{ div } 2) + 1 - 1 && 1 - 1 = 0 \\
 &= 2(n \text{ div } 2) + n \bmod 2 - 1 && n \text{ not even} \\
 &= n - 1 && \text{Lemma 0.1} \\
 &= gn && \text{def } g.
 \end{aligned}$$

In every-day language you are more likely to find the phrase ‘every’ instead of ‘for all’. Mathematicians like to use phrases that are a little bit different from what is common elsewhere to draw attention to the fact that they mean their statement in a formal sense.

**Example 2.20.** ‘Every first year computer science student takes the unit COMP11120’ is a claim that is a ‘for all’ statement. In order to check whether it is true you have to go through all the first year students in the School and check whether they are enrolled on this unit.

In order to show that a statement beginning ‘for all’ does not hold it is sufficient to find *one element* of the given set for which it fails to hold.

**Example 2.21.** In the previous example, if you can find *one* student in computer science who is not enrolled on COMP11120 then you have shown that the statement given above does not hold.

**Example 2.22.** If we claim that for all natural numbers  $m$  and  $n$  it is the case that

$$m - n = m - n,$$

it is sufficient to find *one counterexample*, so by merely writing

$$2 - 1 = 1 \neq -1 = 1 - 2,$$

we have proved that the claim does not hold.

### Key phrase There exists

This is a phrase that is frequently found both in mathematical definitions and arguments.

**Example 2.23.** The definition of divisibility (compare Definition 3)

$m$  is divisible by  $n$

if and only if

~~there exists~~  $k \in \mathbb{N}$   
such that  $m = kn$ .

is an example of a ‘there exists’ statement.

Whenever a statement is made about existence there should be two parts to it:

- **Where does the element exist?** There should always be a set associated with the statement. In the above example,  $k$  had to be an element of  $\mathbb{N}$  (and indeed the existence of some  $r \in \mathbb{R}$  with the same property would completely change the definition and make it trivial).
- **What are the properties that this element satisfies?** There should always be a statement which specifies this. In the example above the property is  $m = kn$  (for the given  $m$  and  $n$ ).

One proves a statement of this form by producing an element which satisfies it, which is also known as a *witness*.

**Example 2.24.** To show that **27 is divisible by 9**, by Definition 3, I have to show that

$$\text{there exists } k \in \mathbb{N} \text{ with } 27 = k9.$$

To show this I offer  $k = 3$  as a witness, and observing that

$$9 \cdot 3 = 27$$

verifies that this element has the desired property.

To go back to the database example you might wonder whether you have a customer in your database who lives in Italy, or whether you have a customer who is paying with cheques (so that you can inform them that you will no longer accept these as a payment method).

Again in every-day language the phrase ‘there is’ is more common than ‘there exists’. The latter serves to emphasize that a statement including is should be considered a precise mathematical statement.

**Example 2.25.** ‘There is a student who is enrolled on COMP25212 and MATH20302’ may have implications for the timetable.

**Example 2.26.** In order to show that there exists a number which is both, even and prime, it is sufficient to supply the witness 2 together with an argument that it is both, even and prime.

Often the difficulty with proving a ‘there exists’ statement is *finding* the witness, rather than with proving that it has the required property.

Sometimes instead of merely demanding the existence of an element we might demand its *unique existence*. This is equivalent to a quite complex statement and is discussed below.

In order to show that a statement beginning ‘there exists’ does not hold one has to establish that it fails to hold for *every* element of the given set. So to demonstrate that the statement above regarding students does not hold you have to check every single second year student.

### Key phrase Unique existence

We sometimes demand that there exists a *unique* element with a particular property. This is in fact a convenient shortcut.

There exists a unique  $s \in S$  with the property  $P$

holds if and only if

there exists  $s \in S$  with property  $P$  and  
for all  $s, s' \in S$ , if  $s$  and  $s'$  satisfy property  $P$  then  $s = s'$ .

**Example 2.27.** If  $f: S \rightarrow T$  is a function from the set  $S$  to the set  $T$  then we know that the function assigns to every element of  $S$  an element of  $T$ , and this means that

for every  $s \in S$  there exists a unique<sup>6</sup>  $t \in T$  with  $fs = t$ .

Uniqueness is important here: We expect that a function, given an input value, produces precisely one output value for that input. So if we have valued  $t$  and  $t'$  in  $T$  which both satisfy the statement then we have  $t = fs = t'$ , and so  $t = t'$ . This idea is used in characterizing graphs of functions on page 42.

### Key phrases: Summary

We have the key ingredients that formal statements are made of, namely the key phrases which allow us to analyse their structure. Analysing the structure of a statement allows us to construct a blueprint for a proof of that statement. The key ideas are given in the text above; we give a summary in form of Table 2.1. By ‘counterproof’ we mean a proof that the statement does not hold. In the table  $S$ ,  $S1$  and  $S2$  are statements, possibly containing further key phrases.

#### Tip

Every statement we might wish to prove, or disprove, is constructed from the key phrases. In order to find a blueprint for a proof, or counterproof, all we have to do is to take the statement apart, and follow the instructions from Table 2.1. We give a number of additional examples for more complex statements in the following sections. Note in particular the proof of Proposition 2.1 as an example of a lengthy proof of this kind.

One shouldn’t think of the above as mere ‘phrases’—they allow us to construct formal statements and come with a notion of how to establish proofs for these. This is what mathematics is all about. We look at an even more formal treatment of these ideas in the material on logic. In

<sup>6</sup>Note that this is a different statement from either Definition 21 or Definition 22—in exams students sometimes get confused about this.

statement	proof	counterproof
$S_1 \text{ and } S_2$	proof of $S_1$ and proof of $S_2$	counterproof for $S_1$ or counterproof for $S_2$
$S_1 \text{ or } S_2$	proof of $S_1$ or proof of $S_2$	counterproof for $S_1$ and counterproof for $S_2$
$\text{if } S_1 \text{ then } S_2$	assume $S_1$ holds and prove $S_2$	find situation where $S_1$ holds and $S_2$ does not
$\text{for all } x, S$	assume an arbitrary $x$ is given and prove $S$ for that $x$	give a specific $x$ and show $S$ does not hold for that $x$
$\text{there is } x \text{ such that } S$	find a specific $x$ and show that $S$ holds for that $x$	assume you have an arbitrary $x$ and show $S$ does not hold for that $x$

Table 2.1: Key phrases and proofs

the following sections we look at examples for such statements which give definitions which are important in their own right. The aim is for you to become familiar with the logical constructions as well as learning about the given example.

## 2.3 Properties of numbers

We begin by giving examples within some sets of numbers. You will need to use the definitions and properties from Chapter 0 here.

In the examples that follow on the left hand side we give running commentary on how to construct the proof that appears on the right hand side.

**Example 2.28.** We prove the following statement for integers  $i$ ,  $j$  and  $k$ :

If  $i$  divides  $j$  then  $i$  divides  $j \cdot k$ .

This is an ‘if ... then’ statement. Table 2.1 above tells us we should assume the first statement holds.

Sooner or later we have to apply the formal definition of divides to work out what this means.

It is usually a good idea to write down what we have to prove, again expanding the definition of ‘divides’.

Assume that  $i$  and  $j$  are integers and that  $i$  divides  $j$ .

By Definition 3 this means that there exists an integer  $m$  such that  $i \cdot m = j$ .

We have to show that  $i$  divides  $j \cdot k$ , and by Definition 3 we have to show that there exists an integer  $n$  such that  $i \cdot n = j \cdot k$ .

We have to establish a ‘there exists’ statement, and Table 2.1 tells us we have to find a witness for which the statement is true. At this point one usually has to stare at the statements already written down to see whether there is an element with the right property hidden among them.

We have

$$\begin{aligned} j \cdot k &= (i \cdot m) \cdot k && \text{assmptn} \\ &= i \cdot (m \cdot k) && \text{Fact 1.} \end{aligned}$$

and so we have found an integer, namely  $m \cdot k$  with the property that we may multiply it with  $i$  to get  $j \cdot k$ .

**Example 2.29.** Assume we are asked to prove

for all  $n \in \mathbb{N}$ ,  $2n$  is even,

Table 2.1 says to show a statement of the form ‘for all ...’ we should assume we have a natural number  $n$ .

So far so good. What about the statement  $2n$  is even? At this point one should always look up the formal definition of the concepts used in the statements.

So now we have put in the definition of evenness, but that leaves us with divisibility, so we put in that definition.

Let  $n$  be in  $\mathbb{N}$ .

We have to show that  $2n$  is even, by Definition 4 this means we have to show that 2 divides  $2n$ .

By Definition 3 we have to show that there is  $k \in \mathbb{N}$  with  $2n = 2k$ . We pick  $k = n$  and so the claim is established.

Sometimes you are not merely asked to prove or disprove a statement, but you first have to work out whether you should do the former or the latter. This changes the workflow a little.

**Example 2.30.** Assume we are asked to prove or disprove the following statement for integers  $i$ ,  $j$  and  $k$ .

If  $i$  divides  $k$ , and  $j$  divides  $k$ , then  $i \cdot j$  divides  $k$ .

Now we first have to work out whether we want to prove the statement, or find a counterproof. Usually it’s a good idea to do some examples. 2 divides 6 and 3 divides 6, and  $2 \cdot 3 = 6$  divides 6, but 2 divides 2 and 2 divides 2, whereas  $2 \cdot 2 = 4$  does not divide 2, so this statement is false.

But what does a formal argument look like in this case? Table 2.1 tells us that it is sufficient to find one way of picking  $i$ ,  $j$ , and  $k$  which makes the claim false.

We show how to use the counterexample we found informally to formally establish that the statement does not hold.

We note that

$$2 \cdot 1 = 2,$$

and so 2 divides 2 by Definition 3. We pick

$$i = j = k = 2.$$

For those choices, the above establishes that  $i$  divides  $k$  and that  $j$  divides  $k$ .

But  $i \cdot j = 4$  and this number does not divide  $k = 2$ , hence the statement is false.

**Example 2.31.** Assume we are given the statement

$$\text{there is an } n \in \mathbb{Z} \setminus \{0, 1\} \text{ such that } n + n = -(n \cdot n).$$

and are asked to prove or disprove it.

Do we believe the statement? If we try  $2+2$  we get 4, but  $-(2 \cdot 2) = -4$ , and clearly we get a sign mismatch if we use any positive integer. But what about  $n = -2$ ?

If we set  $n = -2$  then we have

$$\begin{aligned} n + n &= -2 + (-2) && \text{def } n \\ &= -4 && \text{arithmetic} \\ &= -(2 \cdot 2) && \text{arithmetic} \\ &= -(n \cdot n) && \text{def } n. \end{aligned}$$

as required.

**Exercise 22.** Prove or disprove the following statements about divisibility for integers making sure to use Definition 3. Assume that  $i$ ,  $j$  and  $k$  and  $m$  are integers. Follow the examples above in style (you don't have to give the running commentary).

- (a) If  $i$  divides  $k$  and  $j$  divides  $m$  then  $i \cdot j$  divides  $k \cdot m$ .
- (b) If  $i^2$  divides  $j \cdot k$  then  $i$  divides  $j$  and  $i$  divides  $k$ .
- (c) If  $i$  divides  $j$  and  $j$  divides  $k$  then  $i$  divides  $k$ .
- (d) If  $i$  divides  $j$  and  $j$  divides  $i$  then  $i = j$ .

Here is a definition of a number being prime that will look different from the one you have seen before. The aim of this is to encourage you to follow the given formal definition, and not your idea of what it should mean.

### Definition 16: prime

An element  $n \neq 1$  of  $\mathbb{N}$  (or  $n \neq \pm 1$  in  $\mathbb{Z}$ ) is **prime** if and only if for all elements  $k$  and  $l$  of  $\mathbb{N}$  (or  $\mathbb{Z}$ ) it is the case that

$$n \text{ divides } kl \quad \text{implies} \quad n \text{ divides } k \quad \text{or} \quad n \text{ divides } l.$$

**Example 2.32.** Assume that we have the statement

$$\text{for all } n \in \mathbb{N} \setminus \{0, 1\}, n \text{ is prime or } n \text{ is a multiple of 2.}$$

Do we believe the statement? Well, 0 and 1 have been excluded, so let's look at the next few numbers. We have that 2 is prime, 3 is prime, 4 is a multiple of 2, 5 is prime...

This looks good, but do we really believe this? Are there really no odd numbers which are not prime? The number 9 comes to mind.

So we want to give a counterproof. Table 2.1 tells us that we are looking for one  $n$  such that the statement does not hold.

Let  $n = 9$ .

To give a counterproof we have to show that 9 does not satisfy the claim. The two statements are connected with 'or', so according to Table 2.1 we have to show that *neither* holds.

We note that 9 is not prime since  $9 = 3 \cdot 3$ , so 9 divides  $3 \cdot 3$  but 9 does not divide 3, which means that 9 does not satisfy Definition 16.

If 9 were even it would have to be divisible by 2 according to Definition 4. but since  $9 \bmod 2 = 1$ , Definition 3 tells us that this is not the case.

Hence this is a counterexample to the claim.

**Exercise 23.** Establish the following claims for prime numbers using Definition 16, and definitions and facts from Chapter 0.

(a) Show that if an element  $n$  of  $\mathbb{N}$  is prime then

$$m \text{ divides } n \quad \text{implies} \quad m = 1 \text{ or } m = n.$$

(b) Show that if  $m$  and  $n$  are prime in  $\mathbb{N}$ ,  $m \neq n$ , and  $k$  is any natural number then

$$m \text{ divides } k \quad \text{and} \quad n \text{ divides } k \quad \text{implies} \quad mn \text{ divides } k.$$

(c) Show that if  $n$  is prime in  $\mathbb{Z}$  then

$$m \text{ divides } n \quad \text{implies} \quad m = \pm 1 \text{ or } m = \pm n$$

Note that the converse of (b) and (c) are also true, that is, our definition of primeness is equivalent to the one you are used to. However, the proof requires a lot more knowledge about integers than I want to ask about here.

**Example 2.33.** Assume we are given the statement

There exists  $n \in \mathbb{Z}$  such that  $n$  is a multiple of 3 and  $n$  is a power of 2.

Do we believe the statement? A bit of thinking convinces us that powers of 2 are only divisible by powers of 2, so they cannot be divisible by 3 and therefore they cannot be a multiple of 3.

But how do we show that such a number cannot exist? This is a situation where what counts as a formal proof very much depends on what properties one may use. The cleanest proof is via the prime factorization of integers (or corollaries thereof), but that is more than I want to cover in these notes.

In a situation where you cannot see how to write down a formal proof you should write something along the lines of the first paragraph written here. Never be afraid of expressing your thoughts in plain English!

If you were to start a formal proof it would look like something on the right.

This is where you would like to use that 3 cannot divide  $2^k$ , but this requires a fact that is not given in Chapter 0. So the best you can do is to write what I wrote on the right.

Assume that  $n$  is a power of 2, that is, there exists  $k \in \mathbb{N}$  such that  $n = 2^k$ .

If  $n$  is a multiple of 3 then there is  $l \in \mathbb{Z}$  such that  $n = 3l$ . Hence  $2^k = n = 3l$ .

This means that 3 divides  $2^k$ , which is impossible.

**CExercise 24.** Which of the following statements are valid? Try to give a reason as best you can, following the previous examples. You should use the definitions from Chapter 0 for the notions of evenness and divisibility (and there is a formal definition of primeness below, but for this exercise you may use the one you are familiar with).

- (a) For all  $n \in \mathbb{N}$ ,  $n$  is even or  $n$  is odd.
- (b) There exists  $n \in \mathbb{N}$  such that  $n$  is even and  $n$  is a prime number.
- (c) There exists a unique  $n \in \mathbb{Z}$  such that  $n$  is even and  $n$  is a prime number.
- (d) For all  $n \in \mathbb{Z}$ ,  $n$  is divisible by 4 implies  $n$  is divisible by 2.
- (e) For all  $n \in \mathbb{Z}$ ,  $n$  is odd implies  $n \bmod 4 = 1$  or  $n \bmod 4 = 3$ .
- (f) There exists  $n \in \mathbb{N}$  such that  $n$  is even implies  $n$  is odd.
- (g) For all  $n \in \mathbb{Z} \setminus \{-1, 0, 1, 3\}$  there exists  $m$  in  $\mathbb{Z}$  such that  $n \bmod m = 2$ .

Examples for treating more complex statements, and giving more formal proofs, are given in the following sections.

## 2.4 Properties of Operations

Functions that appear very frequently are *operations on a set*. Usually we are interested in *binary operations on a set  $S$* , that is functions

$$S \times S \rightarrow S.$$

Examples of such functions are

- addition and multiplication for  $\mathbb{N}$ ,
- addition, and multiplication for  $\mathbb{Z}$ ,  $\mathbb{Q}$ ,  $\mathbb{R}$  or  $\mathbb{C}$ , as well as the derived operation of subtraction,
- union and intersection of sets as functions from  $\mathcal{P}X \times \mathcal{P}X$  to  $\mathcal{P}X$ ,
- concatenation of strings in Java,
- concatenation of lists (see Section 6.1) over some set.

Note that we cannot define a division operation for rational, real or complex numbers, in the way that we define subtraction. We may not divide by 0 and so we can only define division it as a function where the source has been adjusted, for example,

$$\begin{aligned} \mathbb{R} \times (\mathbb{R} - \{0\}) : \mathbb{R} &\longrightarrow (x, y) \\ &x \cdot y^{-1}, \longmapsto . \end{aligned}$$

where

$$y^{-1}$$

is our notation for the multiplicative inverse of  $y$ .

These are operations we use all the time, and they are deserving of further study. Note that we typically write binary operations in *infix notation*, that is, we write the operation between its two arguments, such as  $r + r'$ ,  $c \cdot c'$ .

For what follows we need an *arbitrary* binary operation, where we make no assumptions about the kind of operation, or the set it is defined on. For that we use the symbol  $\circledast$ .

### Definition 17: associative

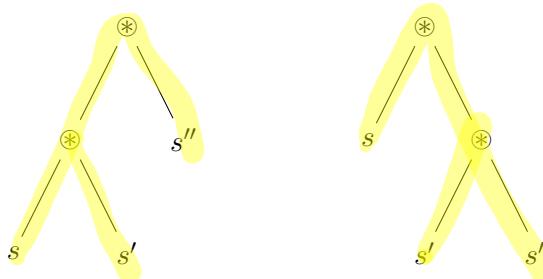

A binary operation  $\circledast$  on a set  $S$  is **associative**<sup>7</sup> if and only, for all  $s$ ,  $s'$ ,  $s''$  in  $S$  it is the case that

$$(s \circledast s') \circledast s'' = s \circledast (s' \circledast s'').$$

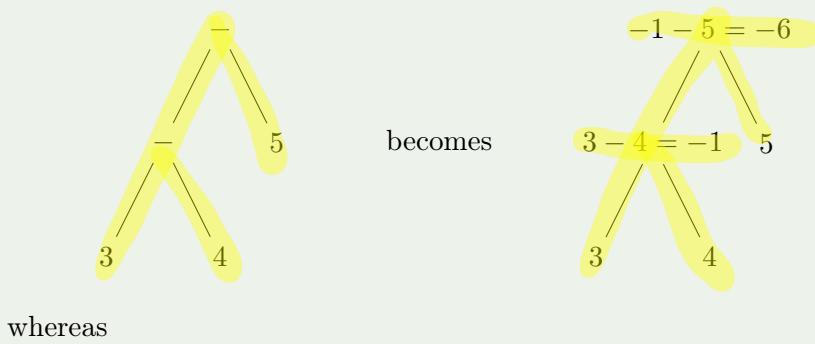

Why is this important? We use brackets to identify in which order the operations should be carried out. We can think of the two expressions as encoding a tree-like structure (known as a *parse tree*<sup>8</sup>), which tells us in which order to carry out the operations present in the expression.

$$(s \circledast s') \circledast s''$$

$$s \circledast (s' \circledast s'')$$

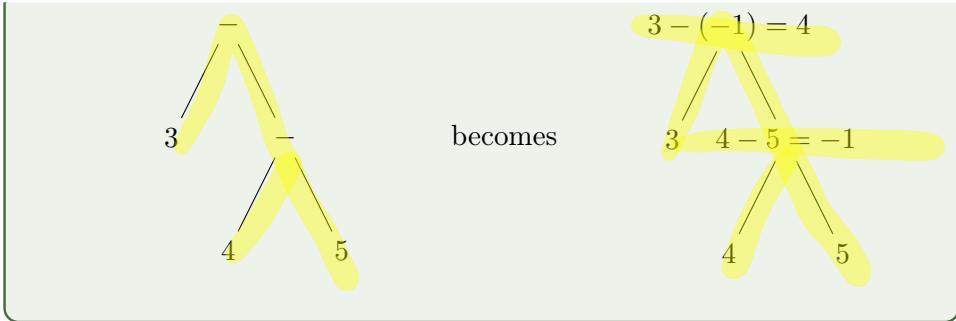

**Example 2.34.** Recall that  $m - n$  is a shortcut for calculating  $m + (-n)$ . Using that derived operation as an example, we illustrate how one can think of this as allowing the filling in of the various steps of the calculation:

<sup>7</sup>Do not confuse this with ‘operator associativity’ from *Java: Just in Time*.

<sup>8</sup>Parse trees are studied in detail in COMP11212.

Knowing that an operation is associative means that both trees evaluate to the same number and therefore we may leave out brackets when using such an operation. It is safe to write

$$s \oplus s' \oplus s''$$

for such an operation.

This is important to computer scientists for two main reasons:

- When writing a program, leaving out brackets in this situation makes the code more readable to humans.
- When writing a compiler for a programming language, knowing that an operation is associative may allow significantly faster ways of compiling.

Note that if we write our operation as a binary function

$$f: S \times S \rightarrow S$$

where we use prefix notation then associativity means that the following equality holds:

$$f(f(s, s'), s'') = f(s, f(s', s''))$$

**Example 2.35.** Assume we are given a set  $X$ . Recall from Section 0.2.4 that we may think of the union operation as a function

$$\cup: \mathcal{P}X \times \mathcal{P}X \longrightarrow \mathcal{P}X.$$

We show that this operation is associative.

The statement we wish to show is a ‘for all’ statement. Following Table 2.1 we assume that  $S$ ,  $S'$  and  $S''$  are (arbitrary) elements  $\mathcal{P}X$ . We calculate

$$\begin{aligned}
 (S \cup S') \cup S'' &= \{x \in X \mid x \in S \text{ or } x \in S'\} \cup S'' && \text{def union} \\
 &= \{x \in X \mid (x \in S \text{ or } x \in S') \text{ or } x \in S''\} && \text{def union} \\
 &= \{x \in X \mid x \in S \text{ or } x \in S' \text{ or } x \in S''\} && \text{common sense} \\
 &= \{x \in X \mid x \in S \text{ or } (x \in S' \text{ or } x \in S'')\} && \text{common sense} \\
 &= S \cup \{x \in X \mid x \in S' \text{ or } x \in S''\} && \text{def union} \\
 &= S \cup (S' \cup S'') && \text{def union}
 \end{aligned}$$

Note that we have justified each step in the equalities used above—this ensures that we check we only use valid properties, and tells the reader why the steps are valid.

Note that we had to invoke ‘common sense’ in the example—usually this means that we are relying on definitions that are not completely rigorous mathematically speaking. What we have done in the definition of the union of two sets is to rely on the meaning of the English language. Only when we are down to that is it allowable to use ‘common sense’ as a justification (you might also call it ‘the semantics of the English language’). In formal set theory there is formal logic to define the union of two sets, but we do not go to this level of detail here.

**Example 2.36.** Example 2.34 establishes that the derived operation of subtraction is *not associative* for the integers since it shows that

$$(3 - 4) - 5 \neq 3 - (4 - 5),$$

and to refute a ‘for all’ claim we merely need to give *one* counterexample.

Since we so far do not have formal definitions of addition and multiplication for  $\mathbb{N}$ ,  $\mathbb{Z}$ ,  $\mathbb{Q}$  and  $\mathbb{R}$  it is impossible to formally prove that these are indeed associative. You may use this as a fact in your work on this unit, apart from when you are asked to formally prove them in Chapter 6.<sup>9</sup>

**CExercise 25.** Work out whether the following operations are associative.

- (a) Intersection for sets.
- (b) Addition for complex numbers.
- (c) Subtraction for complex numbers.
- (d) Multiplication for complex numbers.
- (e) Define the average ave of two real numbers  $r, r'$  as

$$\text{ave}(r, r') = \frac{r + r'}{2}.$$

Is this operation associative? Would you apply it to calculate the average of three numbers? If not, can you think of a better averaging function?

- (f) Multiplication of real numbers where every number is given up to one post-decimal digit, and where rounding takes place every time after a multiplication has been carried out.<sup>10</sup>
- (g) The + operator for strings in Java.
- (h) The && operator for boolean expressions in Java.

<sup>9</sup>Note that formal definitions, and proofs, of these properties for the natural numbers are given in Section 6.4.

- (i) Let  $S$  be a set and let  $\text{Fun}(S, S)$  be the set of all functions with source  $S$  and target  $S$ . Show that composition is an associative operation on the set  $\text{Fun}(S, S)$ .

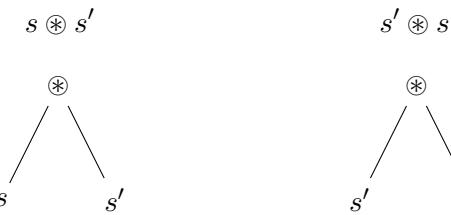

Some operations allow us even greater freedom: Not only is it unnecessary to provide brackets, we may also change the *order* in which the arguments are supplied.

**Definition 18: commutative**

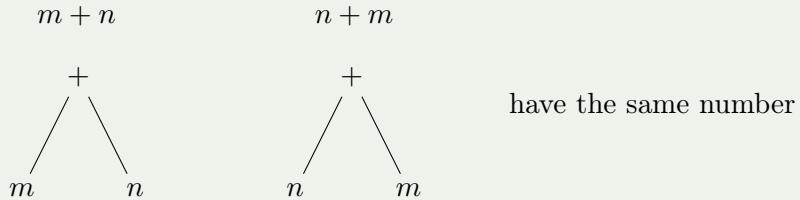

A binary operation  $\circledast$  on a set  $S$  is **commutative** if and only if, for all  $s$  and  $s'$  in  $S$  we have

$$s \circledast s' = s' \circledast s.$$

If an operation is commutative then it does not matter in which order arguments are supplied to it. Hence the two trees below will evaluate to give the same result.

**Example 2.37.** We know that when we have natural numbers  $m$  and  $n$  then

at the root of the tree, and so addition is a commutative operation.

**Example 2.38.** As in Example 2.35 we look at the union operation on the powerset  $\mathcal{P}X$  for a given set  $X$ . We show that this operation is commutative.

Once more this is a statement of the ‘for all ...’ kind. Following Table 2.1 once again we assume that we have (arbitrary) elements  $S$  and  $S'$  of  $\mathcal{P}X$ . The union of  $S$  and  $S'$  is defined as follows:

$$S \cup S' = \{x \in X \mid x \in S \text{ or } x \in S'\}$$

---

<sup>10</sup>When programming there is usually limited precision, and rounding has to take place after each step of the computation. While a computer has more precision, say for floating point numbers, the problems that occur are the same as here.

and, once again invoking ‘common sense’, this is the same as

$$\{x \in X \mid x \in S' \text{ or } x \in S\} = S' \cup S.$$

**Example 2.39.** Consider the following<sup>11</sup> operation for complex numbers: Given  $z$  and  $z'$  in  $\mathbb{C}$  we set

$$z \circledast z' = \bar{z}z'.$$

The question is whether this operation is commutative.

First of all we have to work out whether we think it is true, and should try to prove it, or whether we should aim for a counterproof.

There are two approaches here: You can write down what this operation does in terms of real and imaginary parts which approach we follow in the following example, or you can think for a moment about what the conjugate operation does. It affects the imaginary part only, so if we have the product of one number with imaginary part 0, and one with imaginary part other than 0, there should be a difference. This suggests we should try a counterproof, that is, we should find one choice for  $z$ , and one for  $z'$ , such that the statement becomes false.

The simplest numbers fitting the description given above, and which are distinct from 0, are 1 and  $i$ . We check

$$i \circledast 1 = \bar{i} \cdot 1 = -i \cdot 1 = -i,$$

and

$$1 \circledast i = \bar{1} \cdot i = 1 \cdot i = i.$$

Since  $-i \neq i$  we have established that the given operation is not commutative.

**Example 2.40.** We give an alternative solution to the previous example. We calculate that

$$\begin{aligned} (a + bi) \circledast (a' + b'i) &= (a + bi)\overline{a' + b'i} \\ &= (a + bi)(a' - b'i) \\ &= (aa' + bb') + (-ab' + ba')i, \end{aligned}$$

whereas

$$\begin{aligned} (a' + b'i) \circledast (a + bi) &= (a'a + b'b) + (-a'b + b'a)i \\ &= (aa' + bb') + (ab' - a'b)i \\ &= (aa' + bb') - (-ab' + ba')i. \end{aligned}$$

So the two resulting numbers will have the same real part, but their imaginary parts will be the negatives of each other. Now it is important to remember that it is sufficient to find *just one* counterexample, and it

---

<sup>11</sup>This appeared in a past exam paper.

is best to keep that as simple as possible. We pick

$$a = 0 \quad b = 1 \quad a' = 1 \quad b' = 0,$$

and verify that this means

$$(a + bi) \circledast (a' + b'i) = i$$

and

$$(a' + b'i) \circledast (a + bi) = -i.$$

**CExercise 26.** Work out whether the following operations are commutative. If you think the answer is ‘yes’, give a proof, if ‘no’ a counterexample.

- (a) Multiplication for complex numbers.
- (b) Subtraction for integers.
- (c) Division for real numbers different from 0.
- (d) Set difference on some powerset.
- (e) The ave function from the previous exercise.
- (f) The + operator for strings in Java.
- (g) The && operator for boolean expressions in Java.

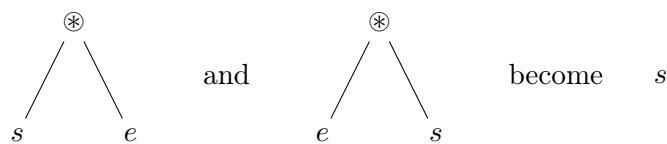

Some operations have an element which does not have any effect when combined with any other.

#### Definition 19: unit

Let  $\circledast$  be a binary operation on a set  $S$ . An element  $e$  of  $S$  is a<sup>12</sup> **unit** for  $\circledast$  if and only if it is the case that for all elements  $s$  of  $S$  we have

$$s \circledast e = s = e \circledast s.$$

If we want to picture this using a tree then it is saying that

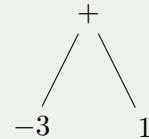

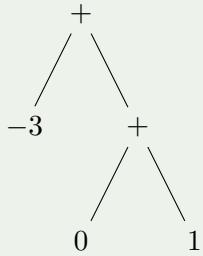

This looks odd, but if you think of the first two trees as being part of a larger tree then this becomes a useful simplification rule.

---

<sup>12</sup>This is sometimes also known as the identity for the unit, but that terminology might create confusion with the identity function for a set.

**Example 2.41.** Knowing that 0 is the unit for addition for the integers we may simplify the tree on the left to become the tree on the right.

**Example 2.42.** We have already seen a number of examples of units. The number 0 is the unit for addition on all the sets of numbers we cover in these notes. This is one of the statements from Fact 1 (and corresponding facts about the other sets of numbers), since for all  $n \in \mathbb{N}$  we have

$$n + 0 = n = 0 + n.$$

**Example 2.43.** If we look at the intersection operation for subsets of a given set  $X$ ,

$$\cap: (S, S') \rightarrow S \cap S',$$

we can show that  $X$  is the unit of this operation. For that we have to calculate, given an arbitrary subset  $S$  of  $X$ ,

$$\begin{aligned} S \cap X &= \{s \in X \mid x \in S \text{ and } x \in X\} && \text{def } \cap \\ &= \{s \in X \mid x \in S\} \\ &= S. \end{aligned}$$

and

$$\begin{aligned} X \cap S &= \{s \in X \mid x \in X \text{ and } x \in S\} && \text{def } \cap \\ &= \{s \in X \mid x \in S\} \\ &= S. \end{aligned}$$

Hence the claim is true.

Working out whether a unit exists for some operation can be tricky. The existence of a unit is equivalent to the statement

there exists  $e \in S$  such that for all  $s \in S$  property  $P$ ,

] where we use ‘property  $P$ ’ as a shortcut. By Table 2.1. to refute such a statement we have show that

for all  $e \in S$  there exists  $s \in S$  property  $P$  does not hold.

Statements like this are quite tricky to prove. In the next two examples you can see us doing it, where we limit the number of elements we have to consider for  $e$  is reduced because we derive some properties it has to satisfy.

**Example 2.44.** Consider the subtraction operation for integers where  $n - m$  is a shortcut for  $n + (-m)$ . Does this operation have a unit? Once again, we first have to decide whether we should try to give a proof or a counterproof.

The statement in question is of the kind ‘there exists ...’. To prove such a statement we have to give an element with the required property. In a situation where we’re not sure what such an element might look like, it is often possible to derive properties it needs to have. This is the strategy we follow here.

If the number we have  $e$  were a unit for subtraction we would require

$$n - e = n$$

for all elements  $n$  of  $\mathbb{Z}$ . The only number which satisfies this is  $e = 0$ , but if we calculate

$$0 - 1 = -1,$$

we see that this element cannot be the unit since we would require that number to be equal to 1 to satisfy  $e - n = n$  for all  $n \in \mathbb{N}$ . Hence the given operation does not have a unit.

Note that the subtraction operation satisfies none of our properties! For this reason it is quite easy to make mistakes when using this operation, and that is why it is preferable to not to consider subtraction a well-behaved operation.

It is usually harder to establish that an operation does not have a unit, so we give another example for this case.

**Example 2.45.** Let us recall the set difference operation from Section 0.2 on  $\mathcal{P}X$  for a given set  $X$  which, for  $S, S'$  in  $\mathcal{P}X$ , is defined as

$$S \setminus S' = \{s \in S \mid s \notin S'\}.$$

Does this operation have a unit? As in the previous example we derive properties that such a unit would have to have.

In order for  $S \setminus S' = S$  to hold it must be the case that none of the elements of  $S$  occurs in  $S'$ . In particular if  $U$  were the unit we must have, instantiating  $S$  as  $X$ ,

$$X \setminus U = \{x \in X \mid x \notin U\} = X,$$

which means that  $U$  must necessarily be empty. But for the empty set we have

$$\emptyset \setminus X = \{x \in \emptyset \mid x \notin X\} = \emptyset,$$

but for  $\emptyset$  to be the unit this would have to be equal to  $X$ .

This means that no element of  $\mathcal{P}X$  can satisfy the requirements for a unit for this operation.

The following exercise asks you to identify units for a number of operations, if they exist.

**EExercise 27.** Identify the unit for the following operations, or argue that there cannot be one:

- (a) Union of subsets of a given set  $X$ .
- (b) Multiplication for integers, rational, real and complex numbers.
- (c) The operation from Example 2.39.
- (d) The ave operation for the preceding two exercises.
- (e) The `+` operator for strings in Java.
- (f) The `&&` operator for boolean expressions in Java.

Note that mathematicians call a set with an associative binary operation which has a unit a **monoid**.

**Exercise 28.** Prove that there is at most one unit for a binary operation  $\circledast$  on a set  $S$ . Hint: Assume you have two elements that satisfy the property defining the unit and show that they must be equal.

**EExercise 29.** Consider the set  $\text{Fun}(S, S)$  of all functions from some set  $S$  to itself. This has a binary operation in the form of function composition. If you have not already done so in Exercise 25 then show that this operation is associative. Find the unit for the operation. Conclude that we have a monoid. Further show that the operation is not commutative in general.

#### Definition 20: inverse element

Let  $\circledast$  be an associative binary operation with unit  $e$  on a set  $S$ . We say that the element  $s'$  is an **inverse for  $s \in S$  with respect to  $\circledast$**  if and only if we have

$$s \circledast s' = e = s' \circledast s.$$

Note that if

$$s^{-1} \quad \text{is the inverse for } s \text{ with respect to } \circledast$$

then

$$s \text{ is the inverse of } s^{-1} \text{ with respect to } \circledast$$

since this definition is symmetric.

It is standard<sup>13</sup> to write  $s^{-1}$  for the inverse of  $s$ , but that convention changes if one uses the symbol  $+$  for the operation. In that case one writes  $-s$  for the inverse of the element  $s$  with respect to the operation  $+$ .

**Example 2.46.** For addition on the integers the the inverse of an element  $n$  is  $-n$ , since

$$n + (-n) = 0 = -n + n,$$

<sup>13</sup>This is the usual notation for  $\mathbb{Q}$ ,  $\mathbb{R}$  and  $\mathbb{Z}$ .

and 0 is the unit for addition. The same proof works for the rationals and the reals. For the complex numbers we have *defined*  $-(a+bi) == a-bi$ , and shown that this is the additive inverse for  $a+bi$  in Exercise 1.1.

**Example 2.47.** For addition on the natural numbers 0 is the unit for addition, but inverses do not exist in general. The number 0 is the only number that has an inverse.<sup>14</sup>

**Exercise 30.** Show that if  $\circledast$  is a binary operation on the set  $S$  with unit  $e$  then  $e$  is its own inverse.

**Example 2.48.** For the rational or real numbers the multiplicative inverse of an element  $r \neq 0$  is  $r^{-1} = 1/r$ . Note that when you use  $r^{-1}$ , or divide by  $r$  you must include an argument that  $r$  is not 0!

**Example 2.49.** In Chapter 1 we have proved that inverses exist for both, addition and multiplication for complex numbers and we have shown how to calculate them for a given element. Recall that if you want to use  $z^{-1}$  you must include an argument that this exists,<sup>15</sup> that is, that  $z \neq 0$ .

**Example 2.50.** The proof that inverses for addition exist for integers, rationals, or reals, is very short: Given such a number  $r$ , we are so used to the fact that  $r + (-r) = 0 = -r + r$  that it hardly feels as if this is a proof!

**Example 2.51.** To show that a given operation does not have inverses for every element one has to produce an element which does not have an inverse.

Assume that  $X$  is a set. Consider the intersection operation,

$$\cap: \mathcal{P}X \times \mathcal{P}X \longrightarrow \mathcal{P}X \\ (S, S') \longmapsto S \cap S'.$$

The unit for this operation is given by  $X$  as established in Example 2.43. We show that the empty set does not have an inverse:

If  $S$  were an inverse for  $\emptyset$  with respect to  $\cap$  it would have to be the case that  $S \cap \emptyset = X$ . But  $S \cap \emptyset = \emptyset$ , and so as long as  $X$  is non-empty, an inverse cannot exist.

---

<sup>14</sup>Think about why that is.

<sup>15</sup>Students have lost marks in exams for just dividing by some number  $z$  without comment.

**Exercise 31.** For the following operations, give an argument why inverses do not exist.

- (a) Union of subsets of a given set.
- (b) The ave function from the previous exercises.
- (c) The + operation for strings in Java.
- (d) The `&&` operation for boolean expressions in Java.

**Exercise 32.** Let  $S$  be a set with an associative binary operation  $\circledast$ , and assume that  $e \in S$  is the unit for that operation.

- (a) Show that the inverse for the element  $s_1 \circledast s_2$  is given by  $s_2^{-1} \circledast s_1^{-1}$ .
- (b) Show that every element has at most one inverse. Hint: Assume that there are two inverses and prove that they have to be the same.

Note that mathematicians call a set with an associative binary operation with a unit, and where every element has an inverse, a **group**. Groups are very nice mathematical entities, but most of the sets with a binary operation you will see will not have the full structure of a group (typically lacking inverses).

**Optional Exercise 7.** Assume that  $A$  is a set with a binary operation  $\circledast$  which is associative and has a unit. Consider the set  $\text{Fun}(X, A)$  of all functions from some set  $X$  to  $A$ . Show that the following definition gives an associative operation on  $\text{Fun}(X, A)$ . For  $x \in X$  set

$$(f \circledast g)x = fx \circledast gx.$$

This is known as defining an operation *pointwise* on a set of functions. Find the unit for this operation and show that it is one. If the operation on  $A$  is commutative, what about the one on  $\text{Fun}(X, A)$ ?

## 2.5 Properties of functions

Functions allow us to transport elements from one set to another. Section 0.3 gives a reminder of what you should know about functions before reading on. Recall Definition 14 which says that the graph of a function

$$f: S \rightarrow T$$

is defined as

$$\{(s, fs) \in S \times T \mid s \in S\}.$$

This is the set we typically draw when trying to picture what a function looks like, at least for functions from sets of numbers to sets of numbers. The typical case for that is for  $S$  and  $T$  to be subsets of  $\mathbb{R}$ .

We can characterize all those subsets of  $S \times T$  which are the graph of a function of the type  $S \rightarrow T$ .

### Proposition 2.1

A subset  $G$  of  $S \times T$  is the graph of a function from  $S$  to  $T$  if and only if  
 for all  $s \in S$  there exists a unique  $t \in T$  with  $(s, t) \in G$ .

This statement requires a proof. We give one here as another example for how to use the key phrases in the statement to structure the proof.

We have an ‘if and only if’ statement, and we split the proof into two parts accordingly.

- Assume that<sup>16</sup>  $G$  is the graph of a function. We would like to have a name for that function, so we call it  $f$ , and note that if  $G$  is its graph then

$$G = \{(s, fs) \mid s \in S\}.$$

We have to show that  $G$  has the given property. This is a statement of the form ‘for all …’, so following Table 2.1 we assume that we have an arbitrary  $s \in S$ . We now have to establish the remainder of the given statement. This is a ‘unique existence’ property, which means we have to show two things:

- **Existence.** In order to show a ‘there exists’ statement Table 2.1 tells us we must find a witness for the variable, here  $t$ , with the desired property. We know that  $(s, fs)$  is in the graph  $G$  of  $f$ , and so we have found a witness in the form of  $t = fs$  for the existence part.
- **Uniqueness.** A uniqueness proof always consists of assuming one has two elements with the given property and showing that they must be equal. Assume we have  $t$  and  $t'$  in  $T$  so that  $(s, t)$  and  $(s, t')$  are both elements of  $G$ . We can see from the equality for  $G$  given above that the only element with first component  $s$  in  $G$  is the element  $(s, fs)$ , and so we must have  $t = fs = t'$  and we have established the uniqueness part.
- Assume that<sup>17</sup>  $G$  is a subset of  $S \times T$  satisfying the given condition. We have to show that  $G$  is the graph of a function, and the only way of doing this is to
  - define a function  $f$  and
  - show that  $G$  is the graph of  $f$ .

We carry out those steps in turns.

- We would like to define a function  $f: S \rightarrow T$  by setting

$$f: s \longmapsto t \quad \text{if and only if} \quad (s, t) \in G.$$

We have to check that this definition produces a function, that is that there is precisely one output in  $T$  for every input from  $S$ . By the existence part of the assumed condition we know that for every  $s \in S$  there is at least one element of  $t$  of

$T$  with  $(s, t) \in G$  and so there is indeed an output for every input. But by uniqueness we know that if  $(s, t)$  and  $(s, t')$  are in  $G$  then  $t = t'$ , so there is at most one element for every  $s \in S$ . Hence given an input our function creates the unique output required.

- It remains to check that  $G$  is the graph of  $f$ , and for that we note that by Definition 14 the graph of a function is given as follows.

$$\begin{aligned} & \{(s, fs) \in S \times T \mid s \in S\} \\ &= \{(s, t) \in S \times T \mid (s, t) \in G\} \quad \text{def } f \\ &= G \end{aligned}$$

This completes the proof.

Our concept of function from Chapter 0 says that a function

$$f: S \rightarrow T$$

produces an output in  $T$  for every input from  $S$ . The proposition above tells us that this means that for every element of  $s$  we have a unique element of  $T$ , namely  $fs$ , which is associated with  $s$ .

Some functions have particular properties that are important to us.

### Definition 21: injective

A function  $f: S \rightarrow T$  is<sup>18</sup> **injective** if and only if

$$\text{for all } s \text{ and } s' \text{ in } S \quad fs = fs' \quad \text{implies} \quad s = s'.$$

Under these circumstances we say that  $f$  is an **injection**.

One way of paraphrasing<sup>19</sup> this property is to say that **two different elements of  $S$  are mapped to two different elements of  $T$** . This means that **knowing the result  $fs \in T$  of applying  $f$  to some element  $s$  of  $S$  is sufficient to recover  $s$** .

**Example 2.52.** The **simplest example** of an injective function is the **identity function**

$$\text{id}_S: S \rightarrow S$$

for any set  $S$ . To prove this formally, note that we have a ‘for all’ statement, so we assume that  $s$  and  $s'$  are elements of  $S$ . We have to prove an implication, so assume the first part holds, that is, we have  $\text{id}_S s = \text{id}_S s'$ . But this implies that

$$s = \text{id}_S s = \text{id}_S s',$$

<sup>16</sup>This direction is sometimes known as the ‘forward’ or ‘if’ direction.

<sup>17</sup>This direction is sometimes known as the ‘backwards’ or ‘only if’ direction.

<sup>18</sup>Note that some people call such functions ‘one-on-one’ instead.

<sup>19</sup>But usually not a good way of attempting a proof.

and so we have  $s = s'$  as required.

**Example 2.53.** The function  $d$  from  $\mathbb{N}$  to  $\mathbb{N}$  given by

$$d: n \longmapsto 2n$$

is injective. To show this we have to show a ‘for all’ statement, so according to Table 2.1 we should assume that we have  $n, n'$  in  $\mathbb{N}$ . To show an implication, the same table tells us we should assume the first part holds, so we assume that

$$dn = dn'.$$

But by inserting the definition of  $d$  this means that

$$2n = dn = dn' = 2n',$$

and by multiplying both sides with the multiplicative inverse of 2 we may conclude that  $n = n'$ .

**Example 2.54.** On the other hand the function from  $\mathbb{R}$  to  $\mathbb{R}$  given by

$$f: r \longmapsto 1$$

is not injective. In order to refute a ‘for all’ statement by Table 2.1 it is sufficient to produce a counter-example. This means we have to find two elements of  $\mathbb{R}$ , say  $r$  and  $r'$ , such that the given implication does not hold.

The same table tells us that for the implication not to hold we must ensure that the first condition is true, which here means that  $fr = fr'$ , while the second condition is false, that is, we must have  $r \neq r'$ .

This is quite easy for our function: The numbers  $r = 0$  and  $r' = 1$  are certainly different, but we have

$$f0 = 1 = f1,$$

so we have indeed found a counterexample.

**Example 2.55.** Typical examples from the real world are unique identifiers, for example, student id numbers. We would expect every student to have a unique id number which is not shared with any other student.

This is certainly a desirable property, but to prove formally that it holds we would have to know how exactly the university assigns these numbers, and then we could check that. Nonetheless you should be able to work out whether real world assignments ought to be injective, and you should be able to come up with ways of testing this realistically, or write a program that confirms it.

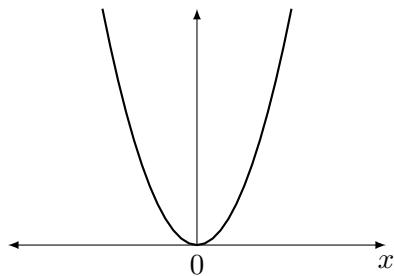

There are many other situations where we have to ensure this—for example, in a database we often want to have a unique key for every entry (for example the customer number).

Also, when casting an element of some datatype to another we expect that if we cast an `int` to a `double` in Java that two different `int` values will be cast to different `double` values. This operation should be performable without losing any information.

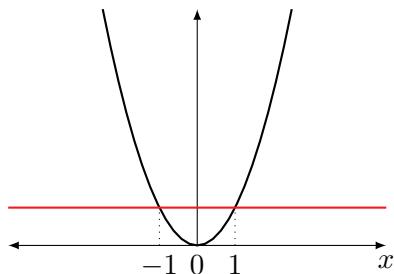

**Example 2.56.** Showing that a real world assignment is not injective has to be done by producing two witnesses. For example, the assignment that maps students to tutorial groups is not injective. To prove that all we have to do is to find two (different) students who are in the same tutorial group. You all know students like that.

We can also think of an injection as a ‘unique relabelling’ function: Every element from the source set  $S$  is given a new label from the target set  $T$  in such a way that no two elements of  $S$  are given the same label.

The graph of a function can be useful when determining whether a function is injective. For the squaring function described above the graph looks like this.

Whenever we can draw a horizontal line that intersects the graph of our function in more than one place then the function is not injective:

The  $x$ -coordinates of the two intersection points give us two different elements of  $\mathbb{R}$  where the function takes the same value, namely here for 1 and  $-1$ , see example 2.57.

Note that one has to be careful when using the graph to determine whether a function is injective: Since most examples have an infinite graph it is impossible to draw all of it, so one has to ensure that there isn’t any unwanted behaviour in the parts not drawn. Further note that a graph cannot provide a *proof* that a function is injective (or not), but it can help us make the decision whether we want to give a proof or a counterproof.

**Example 2.57.** We show that the function whose graph is given above

is not injective. Consider the function

$$\begin{aligned} f: \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto x^2. \end{aligned}$$

Injectivity is a ‘for all’ statement. To give a counterproof by Table 2.1 all we have to do is to find witnesses  $s$  and  $s'$  such that the implication in the definition of injectivity does not hold. So as in Example 2.54 we are looking for two elements, say  $r$  and  $r'$  of  $\mathbb{R}$ , which are different, but which are mapped by the given function  $f$  to the same element.

As suggested by the graph, let  $r = -1$ , and let  $r = 1$ . Then  $fr = (-1)^2 = 1$ , and  $fr' = 1^2 = 1$ , and since  $r = -1 \neq 1 = r'$  we have found a counterexample.

Showing that a function is injective requires more of an argument.

**Example 2.58.** Consider the function

$$\begin{aligned} f: \mathbb{N} &\longrightarrow \mathbb{N} \\ n &\longmapsto 2n. \end{aligned}$$

We show that this function is injective.

Since injectivity is a ‘for all’ statement Table 2.1 suggests that we should assume that we have  $n$  and  $n'$  (arbitrary) in  $\mathbb{N}$ .

We now have to show that the remainder of the statement holds. This is of the form ‘if … then’, and following the same table we assume that  $2n = fn = fn' = 2n'$ . Dividing by 2 on both sides we may conclude that  $n = n'$  as required.

I sometimes see students paraphrase injectivity as ‘for all elements of the source set there is a unique element of the target set which the function maps to’. This is *not* the property of injectivity, this is merely the definition of a function (compare Proposition 2.1). If you want to get full marks for exercises or exam questions you must make sure that you use the definition given above—paraphrasing that definition in an informal way is error-prone.

If you do want to paraphrase injectivity using unique existence, then the valid formulation for a function

$$f: S \rightarrow T$$

is:

for all  $t$  in the image of  $f$

there exists a unique  $s$  in  $S$

such that  $fs = t$ .

**Exercise 33.** Show that the statement above is equivalent to  $f$  being injective.

If there is an injection from some set  $S$  to some set  $T$  then we may deduce that  $T$  is at least as large as  $S$ . See the Section 5.2 for more detail, in particular Definition 42.

**Exercise 34.** Show that the following functions are injective or not injective as indicated.

- (a) Injective: The function from  $\mathbb{R}$  to  $\mathbb{C}$  defined on page 53.
- (b) Not injective: The function  $x \mapsto 2x^2 - 4x + 1$  from  $\mathbb{R}$  to  $\mathbb{R}$ .
- (c) Not injective: The function from the set of first year CS student to lab groups  $M + W$ ,  $B + X$ ,  $Y$  and  $Z$ .
- (d) Injective: The function from  $\mathbb{C}$  to  $\mathbb{C}$  which given by  $x \mapsto \bar{x}$ .

**CExercise 35.** Determine which of the following functions are injective. You have to provide an argument with your answer. You should not use advanced concepts such as limits or derivatives, just basic facts about numbers. Where the function is not injective can you restrict the source set to make it injective?

- (a) The sin function from  $\mathbb{R}$  to  $\mathbb{R}$ .
- (b) The log function from  $[1, \infty)$  to  $\mathbb{R}^+$ .
- (c) The function  $x \mapsto 2^x$  from  $\mathbb{N}$  to  $\mathbb{N}$ , or from  $\mathbb{R}$  to  $\mathbb{R}$ , you may choose.
- (d) The function used by the School from the set of first year CS students to the set of tutorial groups.
- (e) The function used by the University from the set of first year CS students to the set of user ids.
- (f) The function from the set of first year lab groups  $M + W$ ,  $X$ ,  $Y$  and  $Z$  for COMP10120 to their lab slots in the timetable.
- (g) The function  $x \mapsto x(-i)$  from  $\mathbb{C}$  to  $\mathbb{C}$ .
- (h) The function from  $\mathbb{N} \times \mathbb{N}$  to  $\mathbb{N}$  which maps  $(n, m)$  to  $2^n 3^m$ .
- (i) The function  $x \mapsto \{x\}$  from a set  $S$  to the powerset  $\mathcal{P}S$ .

**EExercise 36.** Establish the following properties.

- (a) If  $S$  is a one-element set then every function which has it as a source is injective.
- (b) The composite of two injective functions is injective.

(c) If  $f: S \rightarrow T$  and  $g: T \rightarrow U$  are two functions such that  $g \circ f$  is injective then  $f$  is injective.

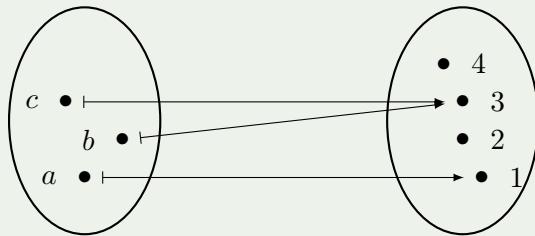

(d) Show for the previous statement that  $g$  need not be injective by giving an example.<sup>20</sup>

(e) Assume that  $f: S \rightarrow S'$  and  $g: T \rightarrow T'$  are both injections. Show that this is also true for

$$f \times g: S \times T \longrightarrow S' \times T'$$
$$(s, t) \longmapsto (fs, gt).$$

In the case where we have a function from one small finite set to another we can draw a picture that makes it very clear whether or not the function is injective.

**Example 2.59.** Consider the function  $f$  defined via the following picture.

We can see immediately that  $b$  and  $c$  are mapped to the same element, 3, and so this function is not injective. Formally, we have found two elements with  $fb = fc$ , but  $b \neq c$ .

If a function is given by a picture like this, then all one has to do to check injectivity is to see whether any element in the target set has more than one arrow going into it. Exercise 41 invites you to try this technique for yourself.

**Exercise 37.** Show that if  $S$  is a set with finitely many elements, and  $f: S \rightarrow T$  is an injective function from  $S$  to a set  $T$  then the image of  $S$  under  $f$  has the same number of elements as  $S$ .

The connection between injective functions and the sizes of sets is further explored in Section 5.2. Here is a second important property of functions.

### Definition 22: surjective

A function  $f: S \rightarrow T$  is<sup>21</sup> **surjective** if and only if

for all  $t \in T$  there exists  $s \in S$  with  $t = fs$ .

We also say in this case that  $f$  is a **surjection**.

<sup>20</sup>The smallest example concerns sets with at most two elements. You may want to read the next two paragraphs to help with finding one.

In other words a function is surjective if its range is the whole target set, or, to put it differently, if its image reaches all of the target set.

We care that a function is surjective if we are using the source set to talk about members of the target set. It means that we can use it to access all the elements of the target set. If you are writing code that has to do something with all the elements of an array, for example, you must make sure that you write a loop that really does go through all the possible indices of the array. If you have programmed a graph, and you want to write an algorithm that visits each element of the graph, you must make sure that your procedure does indeed go to every such node.

**Example 2.60.** Once again, when we have real world example it is impossible to formally prove that a given assignment is a surjective function unless we know how it is defined. However, you should be able to tell whether the assignment ought to be surjective, and you should be able to come up with ways of testing this, and write a program that confirms it. If you construct a mailing list that emails all undergraduate students on a specific course unit you must make sure that your list contains all the students on that course.

**Example 2.61.** The simplest example of a surjective function is the identity function

$$\text{id}_S: S \rightarrow S$$

on a set  $S$ . We give a formal proof.

We have to show a ‘for all’ statement, so let  $s$  in the target of the function, which is  $S$ . We have to find a witness in the form of an element of the source set of the function which is mapped to  $s$ . For this we can pick  $s$  itself, since  $\text{id}_S s = s$ .

**Example 2.62.** Consider the function

$$\begin{aligned} f: \mathbb{N} &\longrightarrow \{2n \in \mathbb{N} \mid n \in \mathbb{N}\} \\ n &\longmapsto 2n. \end{aligned}$$

In order to show that this function is surjective we have to show a statement of the ‘for all there is’ kind. By Table 2.1 we may do this by assuming that we have an arbitrary element for the ‘for all’ part, and then we have to find a witness so that the final part of the statement hold.

So let

$$m \in \{2n \in \mathbb{N} \mid n \in \mathbb{N}\}.$$

By definition this means that there is  $n \in \mathbb{N}$  with  $m = 2n$ . This  $n$  has the desired property since  $m = 2n = fn$ , and so is the required witness.

One can again take the graph of a function to help decide whether a given function is surjective. It can be tricky, however, to determine the answer

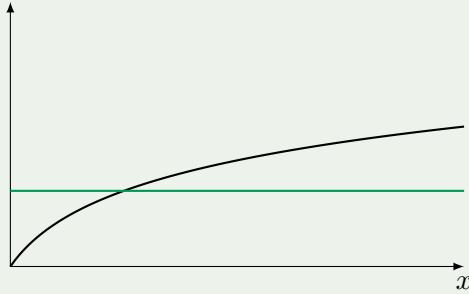

---

<sup>21</sup>Note that some people call such functions ‘onto’ instead.

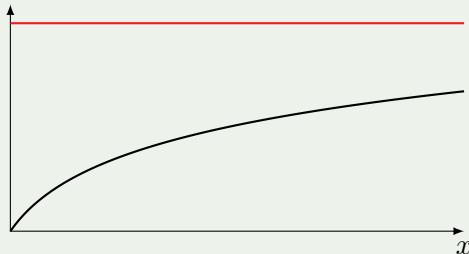

from looking at the graph. Instead of looking whether there is a horizontal line which intersects the graph in at least two points we now have to worry about whether there is a horizontal line that intersects the graph not at all. For some functions this can be quite difficult to see.

**Example 2.63.** Consider for example the function from  $\mathbb{R}^+$  to  $\mathbb{R}^+$  given by

$$x \longmapsto \log(x+1).$$

It is really difficult to judge whether some horizontal line will have an intersection with this graph or not. The picture above tells us that there is a number (namely 3) whose image is 2. But for the picture below it is far less clear whether there is an intersection between the line and the graph of the function.

You might argue that the problem would be solved if we drew a larger part of the graph, but then we could also move the horizontal line higher up (remember that one has to show that one can find an intersection for every horizontal line).

**Example 2.64.** We show formally that a surjective function is given by the previous example,

$$\begin{aligned} f: \mathbb{R}^+ &\longrightarrow \mathbb{R}^+ \\ x &\longmapsto \log(x+1). \end{aligned}$$

We proceed following the same blueprint as in Example 2.62. Let  $r$  be an arbitrary element of the target set  $\mathbb{R}^+$ . We have to find an element  $r'$  of the source set which is mapped to  $r$ , that is we are looking for  $r' \in \mathbb{R}^+$  such that

$$\log(r'+1) = r.$$

We can solve this as an equation where  $r$  is given and  $r'$  is unknown:  
This equation is true if and only if

$$r' + 1 = 2^{\log(r'+1)} = 2^r,$$

which holds if and only if

$$r' = 2^r - 1.$$

Note that it is very easy, in a case like the above, to write something that is *not* a valid proof. The statement we need is that *if* we define

$$r' = 2^r - 1 \quad \text{then} \quad fr' = r.$$

I have seen many student answers which say

$$\log(r' + 1) = r \quad \text{so} \quad r' = 2^r - 1.$$

This does not prove what we need to prove.

It is best if you ensure that that every step you write *implies* the next step that follows on the page.

### Tip

A *correct argument* starts with a *correct statement*, and then applies a number of valid rules to get to the target statement. Implicitly this means that we read such arguments as the current line implying the next one.<sup>22</sup>

If you are constructing an argument which you intend the reader to interpret ‘backwards’, that is, the current line implies the *previous* line you have to indicate this in your text (and make sure your justifications work in the intended direction).

### Example 2.65. The function

$$\begin{aligned} f: \mathbb{Z} &\longrightarrow \mathbb{Z} \\ x &\longmapsto x + 1 \end{aligned}$$

is surjective. Surjectivity is a statement of the ‘for all ...’ kind, so following Table 2.1 we assume we are given  $n \in \mathbb{Z}$ .

The remainder of the surjectivity property is a ‘there exists’ statement, so by to the same table we have to find a witness, say  $m \in \mathbb{Z}$ . This witness has to satisfy  $fm = n$ . Inserting the definition of  $f$ , this means we need to pick  $m$  such that  $m + 1 = fm = n$ , so we pick  $m = n - 1$  and this has the required property, which establishes that  $f$  is surjective.

---

<sup>22</sup>The fact that you can derive a valid statement from the given one does *not* imply anything about the validity of the given statement.

**Example 2.66.** The function

$$\begin{aligned} f: \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto x^2 \end{aligned}$$

is not surjective.

To show this we want to find a counterproof to a statement of the ‘for all ...’ kind. According to Table 2.1 means we have to find a witness  $r$  in the target  $\mathbb{R}$  of the function that does not satisfy the remainder of the property.

Which property is this? It’s a property of the ‘there exists’ kind, so following the same table we have to show that no  $r'$  in  $\mathbb{R}$  satisfies that  $(r')^2 = r$ .

Putting it like this should give us the right idea: We choose  $r = -1$ , and then no real number  $r'$  can be squared to give  $r$ .

Alternatively, looking at the graph of this function, see Example 2.57, we can see that any negative number would work as the required witness.

If there is a surjection from a set  $S$  to a set  $T$  then we may deduce that  $T$  is at most as large as  $S$ . See Lemma 100 in Section 5.2.

**Exercise 38.** Show that the following functions are surjective or not surjective as indicated.

- (a) Surjective: The function  $n \mapsto |n|$  from  $\mathbb{Z}$  to  $\mathbb{N}$ .
- (b) Surjective: The function used by the School from the set of first year CS students to the set of tutorial groups.
- (c) Not surjective: The function used by the University from the set of all students currently in the university to the set of valid student id numbers.
- (d) Not surjective: The function from  $\mathbb{R}$  to  $\mathbb{C}$  given on page 53.

**CExercise 39.** For the following functions determine whether they are surjective and support your claim by an argument. You should not use advanced concepts such as limits or derivatives, just basic facts about numbers.

- (a) The function from  $\mathbb{Q}$  to  $\mathbb{Q}$  given by

$$x \longmapsto \begin{cases} 0 & x = 0 \\ 1/x & \text{else.} \end{cases}$$

- (b) The function from  $\mathbb{R}$  to  $\mathbb{R}$  given by  $x \mapsto x^4 - 100$ .
- (c) The function from  $\mathbb{C}$  to  $\mathbb{C}$  given by  $x \mapsto xi$ .
- (d) The function from  $\mathbb{C}$  to  $\mathbb{R}$  given by  $x \mapsto |x|$ .

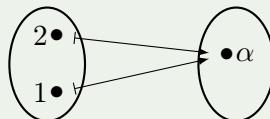

- (e) The function that maps each first year CS student to their labgroup  $W + M$ ,  $B + X$ ,  $Y$  or  $Z$ .
- (f) The function that maps each member of your tutorial group to one of the values  $E$  and  $W$ , depending on whether they were born in Europe ( $E$ ) or in the rest of the world ( $W$ ).
- (g) The function from  $\mathbb{N} \times \mathbb{N}$  to  $\mathbb{N}$  given by  $(x, y) \mapsto x$ .
- (h) The function from the *finite powerset* of  $\mathbb{N}$ ,
- $$\{S \subseteq \mathbb{N} \mid S \text{ has finitely many elements}\},$$
- to  $\mathbb{N}$  that maps  $S$  to the number  $|S|$  of elements of  $S$ .

**Exercise 40.** Establish the following statements

- (a) The composite of two surjections is an surjection.
- (b) If  $f: S \rightarrow T$  and  $g: T \rightarrow U$  are functions such that  $g \circ f$  is surjective then  $g$  is surjective.
- (c) Establish that in the previous statement  $f$  need not be surjective by giving an example.
- (d) Assume that  $f: S \rightarrow S'$  and  $g: T \rightarrow U$  are both surjections. Show that this is also true for  $f \times g$ .

Again, if we are looking at functions between small finite sets then we can easily work out whether a function is surjective by drawing a picture.

**Example 2.67.** Consider the function given by the following diagram.

This function is not surjective since there is no element of the source set that is mapped to the element  $4$  of the target set.

For a function to be surjective all one has to check is that every element of the target set (on the right) has at least one arrow going into it. This example is not surjective.

**CExercise 41.** For the following functions draw a picture analogous to the above and determine whether or not it is injective and/or surjective.

- (a) The function from  $\{0, 1, 2, 3, 4\}$  to itself which maps the element  $i$  to  $i \bmod 3$ .
- (b) The function from  $\{0, 1, 2, 3, 4, 5, 6, 7\}$  to  $\{0, 1, 2, 3\}$  which maps  $x$  to  $x \bmod 4$ .

- (c) The function from  $\{0, 1, 2, 3, 4\}$  to  $\{n \in \mathbb{N} \mid n \leq 9\}$  which maps  $i$  to  $2i$ .
- (d) The function from the set of members of your tutorial group to the set of letters from  $A$  to  $Z$ , which maps a member of the group to the first letter of their first name.
- (e) The function that maps the members of your tutorial group to the set  $\{\text{M}, \text{F}\}$  depending on their gender.
- (f) The function from the set of labgroups

$$\{M + W, B + X, Y, Z\} \quad \text{to the set} \quad \{G23, LF31, \text{both}\}$$

mapping a group to  $G23$  if all their labs for COMP16121 this semester are in  $G23$ , to  $LF31$  if all these labs take place in that room, and to  $\text{both}$  if they have labs in both these rooms.

We need two further notions for functions. First of all there is a name for functions which are both, injective and surjective.

### Definition 2.3: bijective

A function  $f: S \rightarrow T$  is **bijective** if and only if it is both, injective and surjective. We say in this case that it is a **bijection**.

**Example 2.68.** The simplest example of a bijective function is the identity function on a set  $S$ . Examples 2.52 and Example 2.61 establish that this function is both, injective and surjective.

**Example 2.69.** Consider the function  $f$  from  $\mathbb{Z}$  to  $\mathbb{Z}$  given by

$$x \longmapsto x + 1.$$

It is shown in Example 2.65 that this function is surjective and so it remains to show that it is also injective.

Following Table 2.1 to show a ‘for all’ statement we have to assume that we have arbitrary elements  $n$  and  $m$  in  $\mathbb{Z}$ , and that these have the property on the left hand side of the ‘implies’ statement, that is

$$fn = fm.$$

From this we wish to prove  $n = m$ . If we insert the definition of  $f$  then the given equality means that

$$n + 1 = fn = fm = m + 1,$$

and by deducting 1 on both sides we deduce

$$n = m.$$

This establishes that  $f$  is also injective, and so it is bijective.

**Exercise 42.** Determine which of the following functions are bijections. Justify your answer.

(a) The function from  $\mathbb{Q}$  to  $\mathbb{Q}$  given by

$$x \longmapsto \begin{cases} 0 & x = 0 \\ 1/x & \text{else} \end{cases}$$

(b) The function from  $\mathbb{C}$  to  $\mathbb{C}$  given by  $x \mapsto xi$ .

(c) The function from  $\mathbb{Z}$  to  $\mathbb{N}$  given by  $x \mapsto |x|$ .

(d) The function from  $\mathbb{C}$  to  $\mathbb{R}$  given by  $x \mapsto |x|$ .

**Exercise 43.** Show that if  $f: S \rightarrow T$  and  $g: T \rightarrow U$  are two functions and  $g \circ f$  is a bijection then  $f$  is an injection and  $g$  is a surjection.

Recall that we may think of a function that attaches to every element from the source set  $S$  a label from the target set  $T$ . A bijection is a very special such function.

- If the function is *injective* then we know that the label attached to each element of the source set is unique, that is, no other element of that set gets the same label.
- If the function is *surjective* then we know that all the labels from the target set are used.

If we have two sets with a bijection from one to the other then these sets have the same size—this idea is developed in Section 5.1, see in particular Exercise 99.

Whenever we have a bijection  $f$  there is a companion which undoes the effect of applying  $f$ . In other words, we get a function from the target set to the source set which reads the label and gives us back the element it is attached to.

#### Definition 24: inverse function

A function  $g: T \rightarrow S$  is the **inverse of the function** of  $f: S \rightarrow T$  if and only if

$$g \circ f = \text{id}_S \quad \text{and} \quad f \circ g = \text{id}_T.$$

Note that if  $g$  is the inverse function of  $f$  then  $f$  is the inverse function of  $g$  since the definition is symmetric.

**Example 2.70.** Consider the function

$$\begin{aligned} f: \mathbb{Z} &\longrightarrow \mathbb{Z} \\ x &\longmapsto x + 1. \end{aligned}$$

In Example 2.69 it is shown that this function is a bijection. This function has an inverse (and indeed, Theorem 2.3 tells us that every bijection

has an inverse).

To give this inverse we need to find a function which ‘undoes’ what  $f$  does, and the obvious candidate for this is the function  $g$  given by

$$x \longmapsto x - 1.$$

We show that  $g$  is indeed the inverse function for  $f$ . Assume that  $n \in \mathbb{Z}$ . We calculate

$$\begin{aligned} (g \circ f)n &= g(fn) && \text{Definition 12} \\ &= g(n + 1) && \text{def } f \\ &= (n + 1) - 1 && \text{def } g \\ &= n && \text{arithmetic} \end{aligned}$$

and so we know that  $g \circ f = \text{id}_{\mathbb{Z}}$ . We also have to show that the other composite is the identity, so again assume we have  $n \in \mathbb{Z}$ . We calculate

$$\begin{aligned} (f \circ g)n &= f(g(n)) && \text{Definition 12} \\ &= f(n - 1) && \text{def } g \\ &= (n - 1) + 1 && \text{def } f \\ &= n && \text{arithmetic,} \end{aligned}$$

so we also have  $f \circ g = \text{id}_{\mathbb{Z}}$ , and both equalities together tell us that  $g$  is indeed the inverse function for  $f$ .

We illustrate how the properties of a function from  $S$  to  $T$  say something about a function one may construct going from  $T$  to  $S$ : Note that the proposition tells us that for an injective function we can find a function which satisfies one of the two equalities required for inverse functions.

### Proposition 2.2

If  $f: S \rightarrow T$  is an injection then we can find a function  $g: T \rightarrow S$  such that  $g \circ f = \text{id}_S$ .

**Proof.** To start pick an arbitrary element  $s_{\bullet}$  of  $S$ . Now given  $t \in T$  we would like to define  $g$  as follows:

$$g: t \longmapsto \begin{cases} s & \text{if there is } s \in S \text{ with } fs = t \\ s_{\bullet} & \text{else} \end{cases}$$

First of all we have to worry whether this does indeed define a function—we need to ensure that in the first case, only one such  $s$  can exist. But since  $f$  is an injection we know that  $fs = fs'$  implies  $s = s'$  and so  $s$  is indeed unique. Hence our definition does indeed give us a function  $g$ .

Secondly we have to check that the equations for  $f$  and  $g$  holds as

promised. Given  $s \in S$  we calculate

$$\begin{aligned}(g \circ f)s &= g(fs) && \text{def composition} \\ &= s && \text{def } g \\ &= \text{id}_S s && \text{def identity function,}\end{aligned}$$

which completes the proof.

### Theorem 2.3

A function  $f: S \rightarrow T$  is a bijection if and only if it has an inverse function.

**Proof.** We carry out the proof in two parts to reflect the two directions of ‘if and only if’.

Assume that  $f$  is a bijection. This means that, in particular, it is a surjection, so ‘for every  $t$  in  $T$  there is  $s \in S$  with  $fs = t$ . We would like to define  $g: T \rightarrow S$  by

$$t \longmapsto s,$$

for this  $s$ . A priori it is not clear that this defines a function—how do we know that there exists precisely one such  $s$  for each  $t$ ?

Existence follows from surjectivity of  $f$ . Uniqueness comes from injectivity of that function: Assume we have  $s$  and  $s'$  in  $S$  with  $fs = t = fs'$ . This implies  $s = s'$ , and so we have indeed defined a function.

We next show that  $g$  is indeed the inverse of  $f$ .

To show that  $g \circ f = \text{id}_S$  let  $s \in S$ . Then

$$\begin{aligned}(g \circ f)s &= gfs && \text{def function comp} \\ &= s && \text{def } g \\ &= \text{id}_S s && \text{def } \text{id}_S\end{aligned}$$

The last but one step requires further elaboration. Recall that the definition of  $g$  is to map  $t \in T$  to the unique  $s \in S$  with  $fs = t$ . But this means that when  $g$  is applied to an element of the form  $fs$  it returns  $s$ .

To show that  $f \circ g = \text{id}_T$ , let  $t \in T$ . Then

$$\begin{aligned}(f \circ g)t &= f(gt) && \text{def function comp} \\ &= t && \text{def } g \\ &= \text{id}_T t && \text{def } \text{id}_T\end{aligned}$$

Again the last but one step requires further justification. We have defined  $gt$  to be the unique element of  $S$  with  $fs = t$ , so by applying  $f$  on both sides we get  $fgt = t$ .

Now assume that we have an inverse function  $g$  for  $f$ . We have to show that  $g$  is both, an injection and a surjection. For the former, let

$s, s' \in S$  with  $fs = fs'$ . Then

$$\begin{aligned}
s &= \text{id}_S s && \text{def identity function} \\
&= (g \circ f)s && g \circ f = \text{id}_S \\
&= g(fs) && \text{def function composition} \\
&= g(fs') && fs = fs' \\
&= (g \circ f)s' && \text{def function composition} \\
&= \text{id}_S s' && g \circ f = \text{id}_S \\
&= s' && \text{def identity function}
\end{aligned}$$

To see that  $f$  is also surjective, let  $t \in T$ . Then  $f(gt) = t$  since  $f \circ g = \text{id}_T$ , so  $gt$  is an element with the property that applying  $f$  to it results in  $t$ .

Note that if we wish that a function is bijective we may use this result and instead produce an inverse function.

**Example 2.71.** Consider the function

$$\begin{aligned}
f: \mathbb{C} &\longrightarrow \mathbb{C} \\
x &\longmapsto x + i.
\end{aligned}$$

We show that this function has an inverse. We need to find a function that ‘undoes’ the action of  $f$ , which takes a complex number and stretches moves it ‘up’ one unit. To reverse that effect all one has to do is to move it ‘down’ by one unit, so we claim that

$$\begin{aligned}
g: \mathbb{C} &\longrightarrow \mathbb{C} \\
x &\longmapsto x - i
\end{aligned}$$

is the inverse of  $f$ .

The formal proof of this is not long. Based on Definition 24 we have to establish that

$$f \circ g = \text{id}_{\mathbb{C}} \quad \text{and} \quad g \circ f = \text{id}_{\mathbb{C}},$$

which by definition of the equality of two functions (compare Example 2.18) means establishing the two equalities that follow. Let  $z \in \mathbb{C}$ .

$$\begin{aligned}
(f \circ g)(z) &= f(gz) && \text{def funct comp} \\
&= f(z - i) && \text{def } g \\
&= (z - i) + i && \text{def } f \\
&= z.
\end{aligned}$$

$$\begin{aligned}
 (b \circ f)(z) &= g(fz) && \text{def funct comp} \\
 &= g(z + i) && \text{def } f \\
 &= (z + i) - i && \text{def } g \\
 &= z.
 \end{aligned}$$

Hence we may conclude that the function  $f$  is bijective, as is the function  $g$ .

**Exercise 44.** Let  $f: S \rightarrow T$  be a function. Let  $f[S]$  be the image of  $S$  under  $f$  in  $T$  (also known as the range of  $f$ , see Definition 13). We may define a function  $f'$  as follows.

$$\begin{aligned}
 f': S &\longrightarrow f[S] \\
 s &\longmapsto fs.
 \end{aligned}$$

Show that if  $f$  is injective then  $f'$  is a bijection.

**EExercise 45.** Calculate the inverse for the function from  $\mathbb{C}$  to  $\mathbb{C}$  given by  $a + bi \mapsto 2a - b^3i$ . Use the inverse function to show that the given function is surjective.

**Exercise 46.** Recall from Exercise 29 the set  $\text{Fun}(S, S)$  of all functions from a set  $S$  to itself. We define a subset of this set

$$\text{Bij}(S, S) = \{f \in \text{Fun}(S, S) \mid f \text{ is a bijection}\}.$$

Show that the composite of two bijections is a bijection. This means that we can use function composition to define a binary operation

$$\text{Bij}(S, S) \times \text{Bij}(S, S) \rightarrow \text{Bij}(S, S),$$

which is again a monoid. Show that the inverse function of an element of  $\text{Bij}(S, S)$  which is known to exist by Theorem 2.3 is its inverse with respect to the function composition operation. Conclude that  $\text{Bij}(S, S)$  is a group (under the composition operation).

## **Chapter 3**

# **Formal Logic Systems**

This material is now taught by Renate Schmidt, and you will get her notes for the material. A version of this material when it was taught by me is available from the course webpage. This is particularly intended for students on the JH Computer Science and Mathematics programme who do not have access to notes on logic otherwise.

# Chapter 4

## Probability Theory

Probabilities play a significant role in computer science. Here are some examples:

- One mechanism in machine learning is to have *estimates* for the relative probabilities of something happening, and to adjust those probabilities as the system gets more data. The most popular way of doing this is *Bayesian updating*, see Section 4.3.4.
- If you are running a server of some kind you need to analyse what the average, and the worst case, load on that server might be to ensure that it can satisfy your requirements.<sup>1</sup> Calculating such averages is one of the techniques you learn in probability theory.
- When trying to analyse data you have to make some assumptions in order to calculate anything from the data. We look at the question of what assumptions have what consequences.
- In order to calculate the *average complexity* of a program you have to work out how to describe the relative frequency of the inputs, and then calculate the average number of steps taken relative to these frequencies. This means you are effectively the expected value of a random variable (see Section 4.4.6).
- There are sophisticated algorithms that make use of random sampling, such as *Monte Carlo methods*. In order to understand how to employ these you have to understand probability theory.

### 4.1 Analysing probability questions

Before we look at what is required formally to place questions of probability on a sound mathematical footing we look at some examples of the kinds of issues that we would like to be able to analyse.

In computer science we are often faced with situations where probabilities play a role, and where we have to make the decision about how to model the situation.

Every time we are trying to judge the risk or potential benefits of a given decision we are using probabilistic reasoning, possibly without realizing it.

---

<sup>1</sup>You wouldn't want the student system to go down if all students are trying to access their exam timetable at the same time.

We have to come up with a measure of how big the potential benefit, or the potential disadvantage is, and temper that judgement by the likelihood of it occurring.

When somebody buys a lottery ticket, the potential disadvantage is losing their stake money, and the potential advantage is winning something. How many people know exactly what their chances are of doing the latter?

Many games include elements of chance, typically in the form of throwing dice, or dealing cards. When deciding how to play, how many people can realistically assess their chances of being successful?

In machine learning, one technique is to model a situation by assigning probabilities to various potential properties of the studied situation. As more information becomes available, these probabilities are updated (this constitutes ‘learning’ about the situation in question). How should that occur?

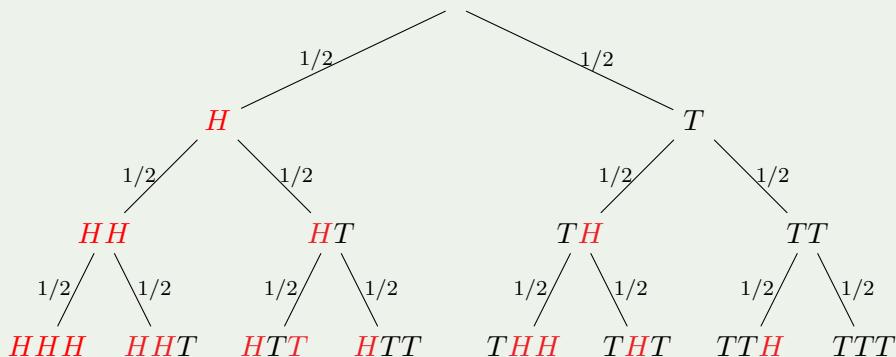

When looking at questions of the complexity of algorithms, one often applied measure is the ‘average complexity’, by which we mean the complexity of the ‘average case’ the program will be applied to. How does one form an ‘average’ in a situation like that?

All these questions are addressed in probability theory, but we have to restrict ourselves here to fairly basic situations to study the general principles. The first few problems we look at are particularly simple-minded.

#### 4.1.1 Simple examples

Most people will have been confronted with issues like the following.

**Example 4.1.** An example much beloved by those teaching probabilities is that of a coin toss. When a fair coin is thrown we expect it to show ‘heads’ with the same probability as tails. For the chances to be even, we expect each to occur with the probability of  $1/2$ . What if we throw a coin more than once? We also expect that the outcome of any previous toss has no influence on the next one. This means we expect it to behave along the following lines.

In order to work out the probability of throwing, say,  $HTH$ , we follow down the unique path in the tree that leads us to that result, and we multiply the probabilities we encounter on the way down, so the probability

in question is

$$\frac{1}{8}.$$

Note that because each probability that occurs in the tree is  $1/2$ , the effect will be that each outcome on the same level will have the same probability, which is as expected.

The tree also allows us to work out what the probability is of having the same symbol three times, that is having

$$HHH \quad \text{or} \quad TTT,$$

which means the event<sup>2</sup>

$$\{HHH, TTT\}$$

occurring. All we have to do is to add up the probabilities for each of the outcomes in the set, so the probability in question is

$$\frac{1}{8} + \frac{1}{8} = \frac{1}{4}.$$

See Section 4.1.4 for more examples where it is useful to draw trees.

**Example 4.2.** Whenever we throw a die, we expect each face to come up with equal probability, so that the chance of throwing, say, a 3 at any given time is  $1/6$ . It is quite easy to construct more complicated situations here. What if we throw two dice? What are the chances of throwing two 1s? What about throwing the dice such that the eyes shown add up to 7? See Exercise 51 and Example 4.22 for a detailed discussion of this particular question.

There are games where even more dice come into the action (for example Risk and Yahtzee), and while computing all probabilities that occur there while you're playing the game may not be feasible, it might be worth estimating whether you are about to bet on something very unlikely to occur.

**Example 4.3.** A typical source of examples for probability questions is as a measure of uncertainty of something happening. For example, a company might know that the chance of a randomly chosen motherboard failing within a year is some given probability. This allows both, the producing company and other manufacturers using the part, to make some calculations regarding how many cases of repairs under warranty they are likely to be faced with.

In particular, if you are a manufacturer seeking to buy 100,000 motherboards, then you have to factor in the costs of using a cheaper, less reliable part, compared with a more expensive and more reliable one. If you have a 10\$ part which has a 5% chance to be faulty within the given period, you would expect to have around

$$100,000 \cdot .05 = 5000$$

<sup>2</sup>This is formally defined in Definition 27—for now just think of it as any set of outcomes.

cases. If on the other hand, you have a 12\$ part that has a 3% chance of being faulty then you will have to pay 200,000\$ more for the parts, and expect to have only

$$100,000 \cdot .03 = 3000$$

cases of failure under warranty. What is the better choice depends on how expensive it is to deal with each case, how many people you expect to make a claim, and whether you worry about the reputation of your company among consumers. Decisions, decisions...

**Example 4.4.** When you are writing software you may wonder how well your program performs on the ‘average’ case it will be given.

For a toy example, assume that your program takes in an input string, does some calculations, and returns a number. The number of calculation steps it has to carry out depends on the length of the input string. You would like to know how many calculation steps it will have to carry out on average so that you have an idea how long a typical call to that program will take.

Assume we have a string of length  $n$ . There is a function which assigns to each  $n \in \mathbb{N}$  the number of calculation steps performed for a string of that length. It may not be easy to *calculate* that function, and you will learn more about how one might do that in both, COMP112 and COMP261. For the moment let’s assume the function in question is given by the assignment

$$n \longmapsto n^2$$

from  $\mathbb{N}$  to  $\mathbb{N}$ .

So now all we need is the average length of an input string to calculate the average number of calculations carried out. But what is that? This will depend on where the strings come from. Here are some possibilities:

- The strings describe the output of another program.
- The strings are addresses for customers.
- The strings encode DNA sequences.
- The strings describe the potential status of a robot (see Example 4.43).
- The strings are last names of customers.

In each situation the average length will be different. You need to know something about where they come from to even start thinking about an ‘average’ case.

If we have a probability for each length to occur then we can calculate an average, see Definition 37 for that.

Note that typically the number of instructions that has to be carried out in a typical computer program depends on more than just the size of the

input. With many interesting algorithms (for example searching or sorting ones) what exactly has to be done depends on the precise nature of the input. See Examples 4.91 and 4.93 for a discussion of two such situations.

### 4.1.2 Counting

When modelling situations using probability we often have to count how many possibilities there are, and how many of those have particular properties.

We give some rules here that help with taking care of this.

#### Selection with return

Assume we are in a situation where there are  $n$  options to choose from, and that we may choose the same option as many times as we like. If we choose  $i$  many times and we record the choices in the order we made them, then there are

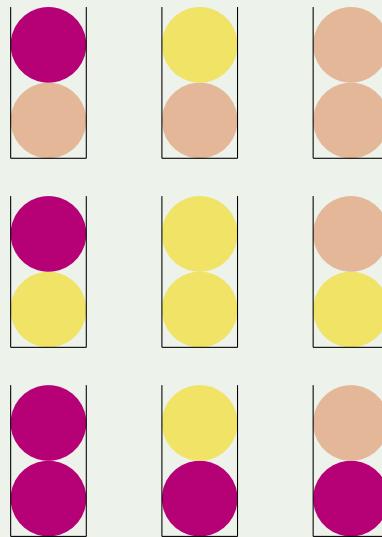

$$n^i$$

possible different possibilities.

**Example 4.5.** If we toss a coin then on each toss there are two options, heads and tails. If we toss a coin  $i$  times then there are  $2^i$  many possible combinations.

**Example 4.6.** Let's assume we have various flavours of ice cream, and we put scoops into a tall glass so that they sit one above each other. If you may choose 3 scoops of ice cream from a total of  $n$  flavours then there are  $n^3$  many combinations, assuming all flavours remain available.

Below we show all the combinations of picking two scoops from three flavours, say hazelnut, lemon, and raspberry.

There are  $3^2 = 9$  possible combinations.

The reason this is known as ‘selection with return’ is that if we think of the choice being made by pulling different coloured balls from an urn (without being able to look into the urn), then one should picture this as drawing a ball, recording its colour before returning it to the urn, drawing a second ball, recording its colour before returning it, and so on.

### Selection without return

If we have a choice of  $n$  possibilities, and we choose  $i$  times in a row, but we may not choose the same item twice, then there are

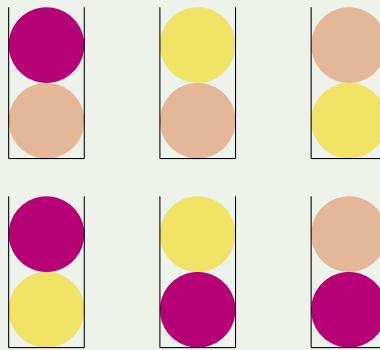

$$n(n-1)\dots(n-i+1) = \frac{n!}{(n-i)!}$$

different combinations, that is listings of choices in the order they were made.

**Example 4.7.** If you have to pick three out of fifteen possible runners to finish first, second and third in that order there are  $15 \cdot 14 \cdot 13 = 2730$  possibilities.

**Example 4.8.** If you have a program that gives you a design for a webpage, where you have to pick three colours to play specific roles (for example, background, page banner, borders), and there are 10 colours overall, then you have  $10 \cdot 9 \cdot 8 = 720$  combinations.

**Example 4.9.** Returning to the ice cream example, if children are given a tall glass in which they each are allowed two scoops from three flavours, but they may pick every flavour at most once (to make sure popular flavours don’t run out) then they have the following choices.

There are now  $3 \cdot 2 = 6$  possibilities.

This is known as selection without return because we can think of it as having an urn with  $n$  differently coloured balls, from which we choose one ball after the other, *without returning them to the urn* and recording the colours in the order they appear.

What happens if the balls don’t each have a unique colour?

## Ordering

If we have  $n$  different items then there are  $n!$  many ways of ordering them, that is, of writing them one after the other. This is the same as choosing without return  $n$  times from  $n$  possible options. If the items are not all different then the number of visibly different possibilities is smaller.

**Example 4.10.** If we have a red, a blue, and three black mugs and we are lining them up in a row then the number of possibilities is

$$\frac{5!}{3!} = 20.$$

There would be  $5!$  possibilities for lining up 5 different mugs, but in each one of those we wouldn't spot the difference if some of the black mugs were swapped. There are  $3!$  ways of lining up the three black mugs (but if we assume that the mugs are indistinguishable then we cannot tell the difference between the different orderings).

In general, if we have  $n$  items and there are  $n_1$  copies of the first design,  $n_2$  copies of the second, and so on, to  $n_i$  items of the  $i$ th design then there are

$$\frac{(n_1 + n_2 + \dots + n_i)!}{n_1! \cdot n_2! \cdot \dots \cdot n_i!}$$

visibly different ways of lining up the items.

## Selection without ordering

Sometimes we are confronted with the situation where we have to count how many different selections there are, but where we are not told the order in which this selection arises. A typical example is a lottery draw:

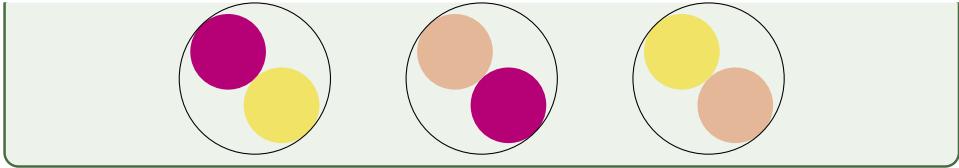

One way of counting these is to list all the options as we have done above, but that gets cumbersome if the numbers involved are bigger. An alternative way of counting is to count how many selections there are with ordering being taken into account, and then dividing by the number of different orderings there are for each choice.

**Example 4.11.** If we return to Example 4.9, then we can look at the situation where the children are given a shallow bowl rather than a tall glass with scoops of ice cream. Again they are allowed to choose two scoops from three flavours, and again they may pick every flavour at most once.

We know from Example 4.9 that there are 6 possible combinations when the order is taken into account. For each choice of two flavours there are two ways of ordering them, so we now have

$$\frac{3 \cdot 2}{2} = 3$$

combinations.

In general, when  $i$  items are picked from a choice of  $n$  different ones, there are

$$\frac{n(n-1)\dots(n-i+1)}{i!} = \frac{n!}{(n-i)!i!}$$

different selections.

### Summary

The formulae given above for the number of possibilities are summarized in the following table. Here  $n$  is the number of items available and  $i$  is the number of items that are selected. Note that the assumption is that in the unordered case, all items are different.

ordered		unordered
with return	without return	
$n^i$	$\frac{n!}{(n-i)!}$	$\frac{n!}{(n-i)!i!}$

Note that there is no simple formula for the number of possibilities there are when looking at unordered selections of items some of which may be identical. In this case the formula for the number of different orderings may be useful. This says that if there are  $n$  items, of which there are  $n_1$  indistinguishable copies of a particular kind,  $n_2$  copies (also indistinguishable among themselves) of a second kind, and so on, with  $i$  many kinds altogether, then there are

$$\frac{(n_1 + n_2 + \dots + n_i)!}{n_1! \cdot n_2! \cdot \dots \cdot n_i!}$$

many visibly different orderings.

**Optional Exercise 8.** Work out why there is no simple formula as described in the previous sentence by looking at some examples.

**Exercise 47.** Assume you have 3 red socks and 5 black ones. Answer the following questions

- (a) Assume we put all the socks into a bag. Four times we draw a sock from the bag, putting it back each time. How many different draws are there?
- (b) Make the same assumption as for the previous part, but now assume we don't put the drawn socks back into the bag. How many draws are there?
- (c) Assume we put the socks onto a pile, close our eyes, mix them around, and pick four socks from the pile. How many different combinations do we get?
- (d) Can you answer the same questions if you assume we have  $m$  red

and  $n$  black socks? What if we pick  $k$  socks (for  $k \leq m+n$ ) many socks on each occasion?

**Exercise 4.8.** A researcher in the rain forest has left his laptop unattended and a curious monkey has come to investigate. When the researcher looks up from the plant he is studying he sees the monkey at the keyboard. He makes threatening noises as he runs back. Assume that every time he shouts there's a 50% chance that he will manage to disrupt the monkey before it makes another key stroke, and that he will have reached the laptop before he has shouted six times. Draw a tree similar to that in Example 4.1 for the situation. What do you think is the average number of key strokes the monkey will manage in this situation?

### 4.1.3 Combinations

Sometimes we have to combine these ideas to correctly count something.

**Example 4.12.** If we throw a coin three times then there are  $2^3$  many possible outcomes. If we want to know how many of those contain at least two heads we have to think about how best to count the number of possibilities.

One possibility is to say that we are interested in

- the situation where there are three heads, of which there is one combination, and
- the situation where there are two heads and one tails. This asks for the number of different ways of ordering  $H, H, T$  and there are

$$\frac{3!}{2!} = 3$$

of those (or there are the positions where the unique  $T$  can go and then the two  $H$  take up the remaining positions).

But this way of thinking does not scale well. What if we want to know how many outcomes have at least 10 heads when we toss the coin 20 times? Following the above idea we have to add up the number of combinations with 20, 19, 18, and so on, down to 10 occurrences of  $H$ .

Or we can argue that there are  $2^{20}$  possibilities overall, of these  $20!/(10! \cdot 10!)$  contain exactly ten times heads and ten times tails and of the remaining combinations half will have a higher count of heads, and half will have a higher count of tails.

There are

$$\frac{20!}{10! \cdot 10!} = \frac{2 \cdot 19 \cdot 2 \cdot 17 \cdot 2 \cdot 15 \cdot 2 \cdot 13 \cdot 2 \cdot 11}{5!} = \frac{19 \cdot 17 \cdot 2 \cdot 13 \cdot 2 \cdot 11}{1} = 184756$$

ways of ordering ten heads and ten tails. The number of combinations of at least 10 heads is then

$$\frac{2^{20} - 184756}{2} + 184756 = \frac{2^{20}}{2} + \frac{184756}{2} = 616666.$$

By thinking about how to count in the right way calculations can be shortened significantly.

**CExercise 49.** Work out how many outcomes there are in the following cases. Please give an expression that explains the number you have calculated.

- (a) Four digit personal identification numbers (PINs). How many times do you have to guess to have a 10% chance of finding the correct PIN?
- (b) How many passwords are there using lower case letters? How many times do you have to guess now to have a 10% chance of being correct?
- (c) What if upper case letters are included?
- (d) How many possible lottery draws are there if six numbers are drawn from 49? How many bets do you have to make to have a 1% chance of having all numbers correct?
- (e) Assume you have an array consisting of 10 different integers. What is the probability that the array is sorted? What happens if the integers are not all different?
- (f) Assume you have an array consisting of 30,000 id numbers. What is the probability that you randomly pick the one you were looking for? What can you say about the case where the array is sorted?
- (g) In an examples class there are 60 students and 6 TAs. Each TA marks 10 students. Assuming the students all have sat down in groups of ten, how many different combinations of TAs and groups are there? What is your chance of having a particular TA this week?
- (h) Assume that there are 6 people who want to randomly split into three teams. For this purpose they put two red, two green and two yellow ribbons into a bag, and each person picks one of those out without looking into the bag.  
What is the probability that Amy will be on the red team? What is the chance that she will be on the same team as Zenia? How many different ways of splitting the six members into teams are there?
- (i) Students from CSSOC are wearing their hoodies. Four of them have a purple, two a green, and one a black one. They line up in a queue to leave the room they are in. What is the probability that all the people in the same colour hoodie are next to each other? What is the probability that no two people wearing a purple hoodie are next to each other?
- (j) Assume you have a monkey that randomly types letters on a keyboard. How many keystrokes does the monkey have to perform to have

a 1% chance to have typed ‘hello’ somewhere in the typed text? You may assume that the keyboard only has lower case letters, and that the space bar is the only non-letter key.

(k) Assume you are at a party. Somebody asks each person when their birthday is. How many people have to be at the party for the probability that two of them share a birthday to be larger than 50%?<sup>3</sup>

(l) Assume you are composing a phrase of music over two four beat bars. You may use one octave, and any duration from a quaver (an eighth note) to a semibreve (a whole note). How many melodies are there?

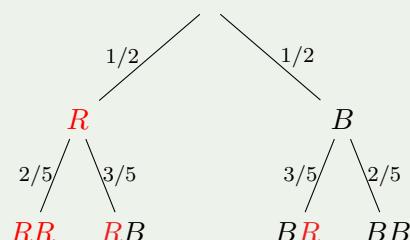

#### 4.1.4 Using trees

Sometimes we can picture what happens in a situation by using trees to provide structure.

**Example 4.13 (Drawing socks).** We may use trees to gain a better understanding of a particular situation. The name ‘decision tree’ is slightly misleading here since we do not just model decisions that somebody might make but also random moves.

Assume you have a drawer with six individual socks, three red and three black (let’s not worry about how you ended up with odd number of socks in both colours). We may answer the question of how many socks we have to pick in order to be sure to get one matched pair—if we pick three socks then there will be at least two which are the same.

But what if we want to know how many socks we have to pick to have a chance of at least 50% of achieving this? We picture our first two draws as follows.

What is the chance of having two socks of the same colour after two attempts? Of the four possible outcomes two are of the kind we want, namely *RR* and *BB*. In order to find out the probability of these two events we *multiply* probabilities as we go down the tree.

- *RR*. The probability for this event is determined by multiplying the probabilities that appear along the path from the root of the tree to that outcome, so it is  $1/2 \cdot 2/5 = 1/5$ .

---

<sup>3</sup>This is known as the *birthday paradox*, although it is not strictly a paradox, merely a question with a surprising answer. It is why computer scientist have to worry about *collisions* when designing hash tables.

- $BB$  The probability is determined in the same way, and also works out to be  $1/2 \cdot 2/5 = 1/5$ .

To calculate the probability of the event of having two socks of the same colour,

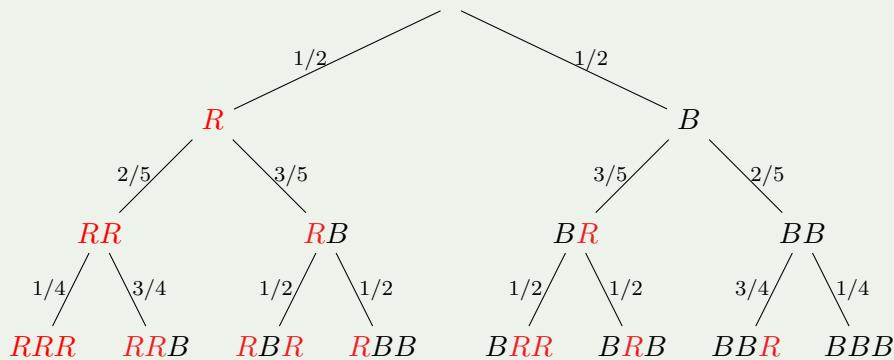

$$\{RR, BB\},$$

we *add* the probabilities of the two outcomes contained, and so we have

$$\frac{1}{2} \cdot \frac{2}{5} + \frac{1}{2} \cdot \frac{2}{5} = \frac{2}{5} = 40\%.$$

Hence in order to guarantee a success rate of at least 50% we have to have (at least) three draws, and in that case we know we will have a 100% success rate.

Let us look at the question of picking at least two black socks. With two draws the chance of succeeding is  $2/10 = 1/5$ . If we add a third draw we get the following.

The outcomes where we have two black socks are

$$\{RBB, BRB, BBR, BBB\},$$

If we add up their probabilities we get

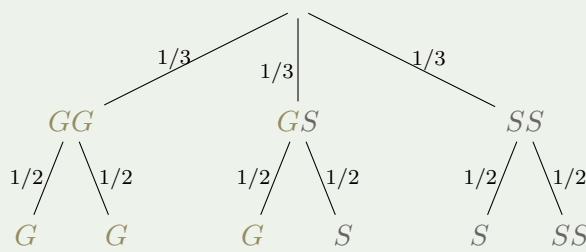

$$\frac{1}{2} \cdot \frac{2}{5} \cdot \frac{3}{4} + \frac{1}{2} \cdot \frac{3}{5} \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{2}{5} \cdot \frac{3}{4} + \frac{1}{2} \cdot \frac{2}{5} \cdot \frac{1}{4} = \frac{3}{20} + \frac{3}{20} + \frac{6}{20} + \frac{1}{20} = 13/20 = 65\%,$$

and that gives us a chance of succeeding which is better than 50%.

**Example 4.14 (Gold and Silver).** Assume there are three bags, each with two coins. One has two coins of gold, another two coins of silver and a third one coin of each kind. Somebody randomly picks a bag, and then draws a coin from the bag without looking inside.

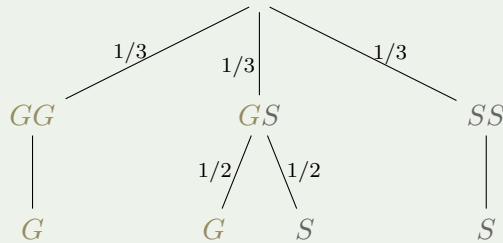

We are shown that the selected coin is gold. What is the chance that the remaining coin from that bag is also gold?

Again we use a tree to understand what is happening.

If we know that a gold coin has been drawn we must be seeing the first, second or third outcome from above. All these are equally likely, with a probability of  $1/6$  each. Two out of the three have a second coin which is also gold, so the desired probability is  $2/3$ .

Instead of explicitly looking at both coins in the bag, as we did in the tree above, we could have a different event, namely the colour of the drawn coin. If those are our chosen outcomes then the corresponding tree looks like this.

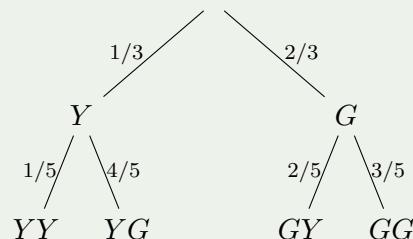

Now we argue that knowing the drawn coin is gold tells us that we have either the first or the second outcome. The former occurs with probability  $1/3$ , the second with probability  $1/6$  overall, so the former is twice as likely as the latter, again giving a probability of  $2/3$  that the second coin is also gold.

**Example 4.15.** Bonny<sup>4</sup> and Clyde are playing a game. They put two yellow and four green ribbons into a bag. Without looking inside, each of them reaches into the bag and draws a ribbon.

If the ribbons have the same colour Bonny wins and if they are different, then Clyde wins. We want to know whether the game fair, that is, if they both have an equal chance of winning.

This question is much easier to answer if we draw a tree.

From the tree we can read off that the probability of drawing the same

colour, the event  $\{YY, GG\}$ , has the probability

$$\frac{1}{3} \cdot \frac{1}{5} + \frac{2}{3} \cdot \frac{3}{5} = \frac{7}{15},$$

while the probability of drawing different colours, the event  $\{YG, GY\}$ , has the probability

$$\frac{1}{3} \cdot \frac{4}{5} + \frac{2}{3} \cdot \frac{2}{5} = \frac{8}{15}.$$

The two numbers are different and so the game is not fair. Clyde has a higher chance of winning.

**Example 4.16 (The Monty Hall problem).** A well-known problem that we may use for illustrative purposes is known as the *Monty Hall problem*. This example also occurs in COMP14112,

Imagine you are in a game show. There are three closed doors labelled  $A$ ,  $B$  and  $C$ , and you know that behind one of them is a valuable prize (in the original story a car) and behind two of them is something not worth having (in the original story a goat).

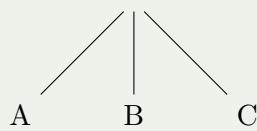

The way the game works is that you pick a door, and then the show master opens one of the remaining doors. You see the booby prize. You are now offered the chance to switch to the other closed doors. Should you switch, or stick with your original choice?

This situation has been endlessly discussed among various groups of people, often because somebody knows the solution and somebody else doesn't want to believe it.

So how does one model a situation like that reliably? Usually when there are steps in a situation it is worth modelling these steps one by one.

What do we know for sure? We know that at the beginning there are three doors, let's assume with two goats and a car. We assume that the probability of the car being behind any one of the doors is the same. From the point of view of the contestant this is like a random event. The production company picks an actual door, and there is no way of telling how they decide which one to hide the main prize behind, but one might hope that they really do pick any door with the probability of  $1/3$ , and that's the assumption the contestant should make. The action of the show master afterwards has to depend on the choice made by the contestant, and we make the additional assumption that if the show master has a choice of opening a door he will open them with equal probability.

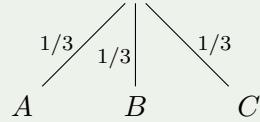

We can model the choices step by step using a tree. In the first step we model the fact that the car might be behind any one of the doors.

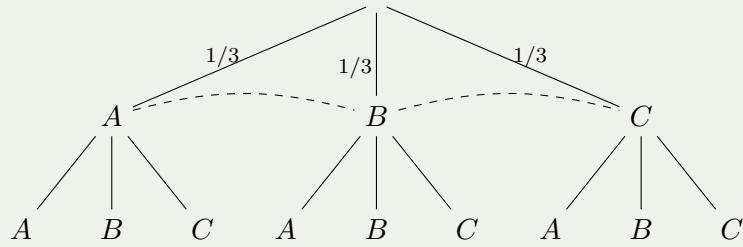

---

<sup>4</sup>This is a past exam question.

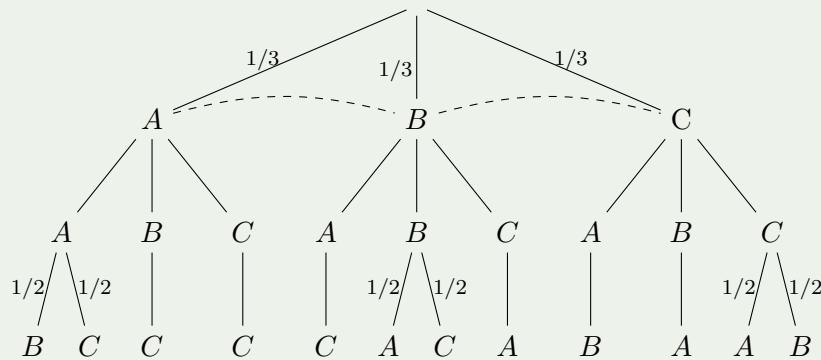

We put probabilities in the tree which indicate that the car can be behind each of them with equal probability.

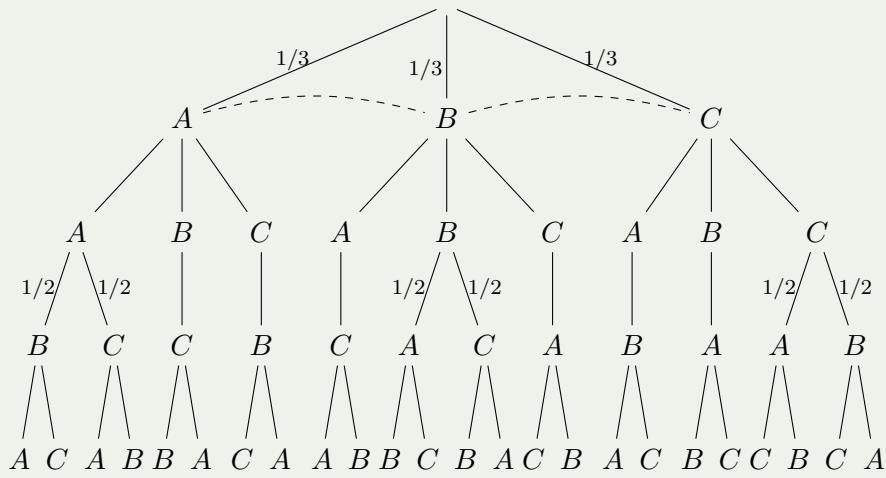

There are three possibilities for the player to choose a door. But note that the player does not know which of these three positions she is in. In game theory one says that the leaves of the tree are in the same *information set*. So from the player's point of view there are three choices (pick door A, B or C), and she cannot make that dependent on where the car is since she does not have that information. This is similar to the situation in many card games where the player has to choose what to play without knowing where all the cards are situated. Only in the course of further play does it become clear what situation the players were in. In the tree we denote this by a dashed line connecting the positions which the player cannot distinguish.

The next step is for the show master to open one of the doors showing the booby prize. In some cases there is only one possible door to open, in others there is a choice between two, and we assume that he picks either one of them with equal probability.

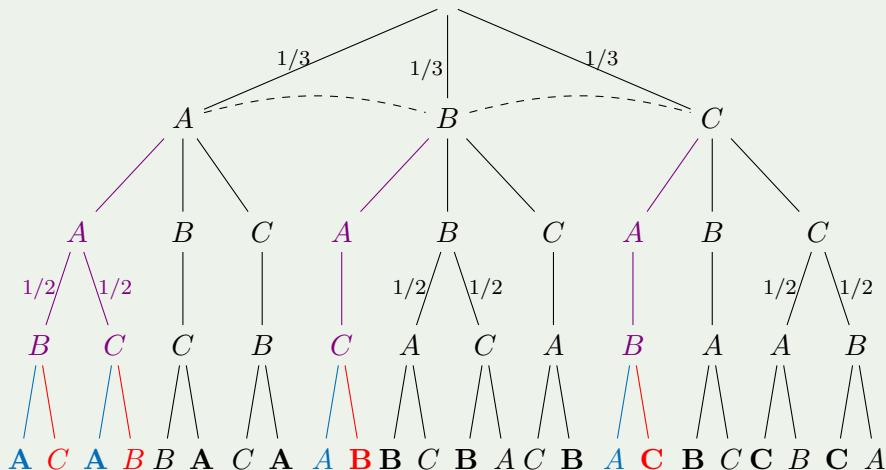

Now the player has to decide whether she wants to switch or not. Again we draw the possible options. We first give the door where the player has not switched, and then the one where she has.

We note that the three principal subtrees are the same up to renaming of nodes. This is because from the Player's point of view, there are only three options (which door to pick), and the first step drawn in the tree (the selection of the door which hides the prize) is completely hidden. The result of that step is not revealed to the player until the end of the game. We look at the question of what happens if the player switches or sticks with her first choice. In purple we highlight the case where the player's first choice is A. The remaining two possibilities give the same result. We also highlight those position where the player wins the main prize by giving it in bold. We now look at two strategies:

- Pick *A* on the first move and then stick with this choice, given in blue (this is the left choice in the fourth layer of the tree).
- Pick *A* on the first move and then switch when given the chance to do so, given in red (this is the right choice in the fourth layer of the tree).

If the player picks door *A* on the first move, and then sticks to that choice, there is a chance of  $1/3$  that the original choice was correct, and then no matter which door is opened the main prize is achieved. So

a player who does not switch will get the main prize with probability of  $1/3$ .

A player who picks door  $A$  on the first move and then switches, had the correct door with probability  $1/3$  and then switches away, which means that he obtains the main prize with probability  $2/3$ .

For this reason a player who picks a door and then switches has a chance which is twice as high to get the main prize than the player who sticks.

Note that in particular we can see from this example that it may be that what looks like one choice to the player (for example ‘pick door  $A$ ’) is effectively a choice taken in a number of different situations the player cannot distinguish between (here the player does not know behind which door the prize is hidden)—in that case the choice will be reflected in several subtrees.

Note that we can tell if a tree properly describes a probabilistic situation:

#### Proposition 4.1

A tree with probabilities along some of the edges describes a situation of choices and probabilistic moves if and only if for every node in the tree the probabilities of the edges going down from that node add up to 1.

**CExercise 50.** Suppose we have a deck of four cards,

$$\{Q\spadesuit, A\spadesuit, Q\heartsuit, A\heartsuit\}.$$

I draw two cards from this pack without being able to see the front of the cards.

You ask me whether one of my cards is an ace, and I answer in the affirmative.

You then tell me to drop one of my cards, making sure I keep an ace in my hand.

You ask me whether I have the ace of spades  $A\spadesuit$ , and I answer yes.

What is the probability that the card I dropped is also an ace? *Hint: Draw a tree, but note that if you read the given information carefully you don't have to draw all of it. How many different draws are there? You'll make your life more complicated if your tree contains more nodes than needed.*

**Exercise 51.** Assume you are throwing two dice, a red and a blue one.

- What is the probability that the sum of the eyes is exactly 4?
- What is the probability that the sum of the eyes is at least seven?
- What is the probability that there is an even number of eyes visible?
- What is the probability that the number on the red die is higher than that on the blue?

#### 4.1.5 Further examples

In the previous sections it was clear from the context which principles you had to apply to find a solution. The point of the following exercises is that you first have to think about what would make sense in the given situation.

**EExercise 52.** Assume two teams are playing a ‘best out of five’ series which means that the team that wins three matches is the winner of the series. Once it is clear that one side has won, the remaining matches are no longer played. For example, if one team wins the first three matches the series is over.

- (a) Assume that the two teams are equally matched. After what number of matches is the series most likely to end?
- (b) How does the answer change if the probability of one team winning is 60%?

**Exercise 53.** Solve the same problem as for the previous exercise, but with a ‘best out of seven’ series.

**CExercise 54.** Imagine you have a die that is loaded in that even numbers are twice as likely to occur than odd numbers. Assume that all even numbers are equally likely, as are all odd numbers.

- (a) What is the probability of throwing an even number?
- (b) What is the probability that the thrown number is at most 4?
- (c) With two dice of this kind what is the probability that the combined number of eyes shown is at most 5?

**Exercise 55.** Assume you have a coin that shows heads half the time and tails the other half, also known as a *fair coin*. Assume the coin is thrown 10 times in a row.

- (a) What is the probability that no two successive throws show the same side?
- (b) What is the probability that we have exactly half heads and half tails?
- (c) What is the chance of having at least five subsequent throws showing the same symbol?

**Exercise 56.** Assume we toss a fair coin until we see the first heads. We want to record the number of tosses it takes. What is the probability that we require 10 tosses or more?

## 4.2 Axioms for probability

In the examples above we have assumed that we know what we mean by ‘probability’, and that we have some rules for calculating with such numbers.

### 4.2.1 Overview

This section puts these intuitive ideas onto a firm mathematical footing. It does so in a very general way which you may find difficult to grasp. However by setting this up so generally we give rules that can be applied to *any* situation. Thinking about these rules also encourages you to think about how to model specific situations you are interested in, and to take care with how you do so.

The idea underlying probability theory is that we often find ourselves in a situation where we can work with

- a *sample space*  $S$  of all possible outcomes,
- a *set of events*  $\mathcal{E}$  (which is a subset of the powerset of  $S$ ) and
- a *probability distribution* which is given by a function

$$P: \mathcal{E} \rightarrow [0, 1],$$

where  $[0, 1]$  is the interval of real numbers from 0 to 1.

**Example 4.17.** The simplest kind of probability space is one where there are  $n$  options, say

$$S = \{s_1, s_2, \dots, s_n\},$$

and all these occur with equal probability. In this case the set of events is the set  $\mathcal{PS}$  of all subsets of  $S$ , and the probability distribution

$$P: \mathcal{PS} \rightarrow [0, 1]$$

is given by the assignment

$$S \longmapsto \frac{|S|}{n},$$

that is, every set is mapped to its number of elements divided by  $n$ .

We give precise definitions of what we mean with these notions below, but for the moment let’s look at a slightly more complicated example.

**Example 4.18.** In a simple dice game the participants might have two dice which they throw together. If the aim of the game is to score the highest number when adding up the faces of the dice then it makes sense to have the possible outcomes

$$S = \{2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\}.$$

We call the set of possible outcomes the *sample space*  $S$ . We could now

ask what the probability is of throwing at most 5, which is the event

$$\{2, 3, 4, 5\}.$$

This example is continued below.

Typically when we have a finite set of outcomes  $S$  we assume that the set of events  $\mathcal{E}$  is the whole powerset  $\mathcal{P}S$ . When we have an infinite set of outcomes this is not always possible. There is a field in mathematics called *measure theory* which is concerned with which sets of events can be equipped with probability functions, but that goes beyond this course.

Often it is possible to make the sample space finite, and this frequently (but not always) happens for computer science applications.

**Example 4.19.** In COMP14112 you will be looking at a program that learns the location of a robot in a two-dimensional space. If we think of the location as being given by two coordinates, and the coordinates as real numbers, then there are uncountably many locations in the unit square

$$[0, 1] \times [0, 1].$$

But we cannot measure the location of the robot up to infinite precision (and indeed, we're not interested in the answer to that level of precision), and in the robot exercise a  $100 \times 100$  grid is imposed on the space, and we are only interested in which one of the squares in the grid the robot inhabits. This means the sample space now has only  $100 \cdot 100 = 10,000$  elements.<sup>5</sup>

**Example 4.20.** If you are interested in the price of a commodity, it typically makes sense to measure the price only up to a limited precision (typically a few post decimal digits), and again this has the effect of making the sample space finite.

We consider many finite sample spaces in this chapter, but we do have a look at infinite notions as well since that also occurs in some applications in computer science. For this reason we here give definitions which are general enough to apply to both cases.

**Example 4.21.** When we consider events that happen over a given time frame it is often more convenient to treat that time frame as a real interval,  $[r, r']$ , where  $r$  is the start time and  $r'$  is the end time. The reason for this is that the entities we would like to compute can typically be computed with the help of integrals. These ideas are pursued in Examples 4.27, 4.28 and 4.81 and Exercises 60 and 84.

Not every function satisfies the requirements of a probability function, and we look at what properties we expect below. In order to formulate what we expect from a probability function  $P$  we first have to look at what we expect from the set of events.

<sup>5</sup>See Example 4.43 for a simplified version of this scenario.

### 4.2.2 Events and probability distributions

The following two definitions are given here for completeness' sake.<sup>6</sup> Above we did not worry about the properties required of probability distributions, and we also did not wonder whether a given set of outcomes could be an event, or not.

When we wish to consider a sample space that is uncountable<sup>7</sup>, for example the real interval  $[0, 1]$ , it is difficult to find a probability space for this set of outcomes. There are two difficulties:

- If we want to assign the same probability to each element of  $[0, 1]$  then this probability *has* to be 0 (otherwise the probability for the whole interval would be infinite, compare Proposition 4.4). The only way of defining a probability function with this property is to define a function that takes as its input events (that is, sets of outcomes).
- It is not possible to give a probability distribution that assigns a probability to *every* subset of  $[0, 1]$ , see Proposition 4.5. How to define a probability space in this situation is sketched in Proposition 9. It has the property that the probability of any interval  $[r, r']$  in  $[0, 1]$  has a probability proportional  $r' - r$ , that is, its probability is determined by its length.

For this reason we describe here which collection of subsets of the sample space is suitable to form a probability space.

#### Definition 25: $\sigma$ -algebra

Let  $S$  be a set. A subset  $\mathcal{E}$  of  $\mathcal{P}S$  is a  $\sigma$ -algebra provided that

- the set  $S$  is in  $\mathcal{E}$ ,
- if  $E$  is in  $\mathcal{E}$  then so is its complement  $S \setminus E$  and
- if  $E_i$  is in  $\mathcal{E}$  for  $i \in \mathbb{N}$  their union  $\bigcup_{i \in \mathbb{N}} E_i$  is in  $\mathcal{E}$ .

We note some consequences of this definition. First of all, since  $S$  is in  $\mathcal{E}$  we may form its complement to get another element of  $\mathcal{E}$ , and so

$$\emptyset = S \setminus S$$

is in  $\mathcal{E}$ .

Further note that the union of a finite number of events must also be an event: If we have events  $E_0, E_1, \dots, E_n$  then we can set  $E_i = \emptyset$  for  $i > n$ , and then

$$\bigcup_{i \in \mathbb{N}} E_i = E_0 \cup E_1 \cup \dots \cup E_n.$$

Note that for every set  $S$  the powerset  $\mathcal{P}S$  is a  $\sigma$ -algebra.

Events which are disjoint play a particular role: If we have two sets of possible outcomes, say  $E$  and  $E'$ , and these sets are disjoint, then we expect that the probability of  $E \cup E'$  is the probability of  $E$  added to that of  $E'$ . But this is not a property of just two sets of outcomes—sometimes we need

<sup>6</sup>In particular these two definitions are not part of the examinable material.

<sup>7</sup>See Definition 45—for now stay with the example of the unit interval.

to apply it to larger collections of sets. This means we have to worry about what the appropriate generalization of ‘disjoint’ is.

If we have three sets of outcomes, events  $E$ ,  $E'$  and  $E''$ , then in order for

$$P(E \cup E' \cup E'')$$

to be equal to

$$PE + PE' + PE''$$

to hold it must be the case that none of these sets ‘overlap’, in other words, we need that

$$E \cap E' = \emptyset, \quad E \cap E'' = \emptyset, \quad E' \cap E'' = \emptyset.$$

If we want to apply this to even more sets we really need to use a general definition.

### Definition 26: pairwise disjoint

Let  $S$  be a set. Further assume that we have an arbitrary set  $I$ , and that for each element  $i \in I$  we have picked a subset  $S_i$  of  $S$ . We say that the collection of the  $S_i$ , where  $i \in I$ , is **pairwise disjoint** if and only if

$$\text{for } i, j \in \mathbb{N} \text{ we have } i \neq j \text{ implies } S_i \cap S_j = \emptyset.$$

This means that the sets we have picked for different elements of  $I$  do not overlap.

**Exercise 57.** Assume that we have a set  $S$ . We are also given two disjoint subsets  $B_1$  and  $B_2$  of  $S$  and a collection  $E_i$ , for  $i \in \mathbb{N}$ , pairwise disjoint subsets of  $S$ .

- (a) Show that for  $A \subseteq S$  we have that  $A \cap B_1$  and  $A \cap B_2$  are disjoint.  
*If you can do the next part without doing this one you may skip it.*
- (b) Show that for  $A \subseteq S$  we have that  $A \cap E_i$  is a collection of pairwise disjoint sets.
- (c) Show that for  $A \subseteq S$  we have that

$$A \cap (B_1 \cup B_2) = (A \cap B_1) \cup (A \cap B_2).$$

*If you can do the next part without doing this one you may skip it.*

- (d) Show that for  $A \subseteq S$  we have that

$$A \cap \bigcup_{i \in \mathbb{N}} E_i = \bigcup_{i \in \mathbb{N}} (A \cap E_i).$$

- (e) Show that if  $A \subseteq B_1 \cup B_2$  then  $A$  is the disjoint union of  $A \cap B_1$  and  $A \cap B_2$ .  
*If you can do the next part without doing this one you may skip it.*

- (f) Show that if  $A \subseteq \bigcup_{i \in \mathbb{N}} E_i$  then  $A$  is the disjoint union of the  $A \cap E_i$ .

### Definition 27: probability space

A **probability space** is given by

- a *sample set*  $S$ ;
- a *set of events*  $\mathcal{E} \subseteq \mathcal{P}S$  which is a  $\sigma$ -algebra and
- a *probability distribution*, that is a function

$$P: \mathcal{E} \rightarrow [0, 1],$$

with the properties that

- $P_S = 1$  and
- given  $E_i$ , for  $i \in \mathbb{N}$ , pairwise disjoint<sup>8</sup>, then<sup>9</sup>

$$P(\bigcup_{i \in \mathbb{N}} E_i) = \sum_{i \in \mathbb{N}} P(E_i).$$

These axioms for probability go back to the Russian mathematician *Andrey Kolmogorov* who was trying to determine what the rules are that make probabilities work so well when describing phenomena from the real world. His rules date from 1933. What we have done here is translate them into a more modern setting.

These axioms may seem complicated, but they are quite short, and they have a lot of consequences which you may have learned about when studying probability previously. We look at these in the following section.

**Optional Exercise 9.** In the definition of a probability distribution we can see an infinite sum. Under which circumstances does it make sense to write something like that? Try to find a probability distribution for the natural numbers, with  $\mathcal{P}\mathbb{N}$  as the set of events. *Hint: It is sufficient to give probabilities for events of the form  $\{n\}$ .*

**Optional Exercise 10.** Assume you want to find a probability distribution for the sample space  $[0, 1]$  with a  $\sigma$ -algebra which contains all sets of the form  $\{r\}$  as events. What can you say about the probabilities of these sets?

**Optional Exercise 11.** Assume you are given the sample set  $[0, 1]$  and you know that every interval in  $[0, 1]$  is an element of the  $\sigma$ -algebra  $\mathcal{E}$ . Further assume that you are being given a probability distribution on  $\mathcal{E}$  which maps every interval  $[r, r']$  in  $[0, 1]$  to  $r' - r$ . Convince yourself

<sup>8</sup>Note that some authors write a disjoint union using the addition symbol  $+$ , and  $\sum$  for infinite such unions, but we do not adopt that practice here in case it causes confusion.

<sup>9</sup>Note that below appears a potentially infinite sum, that is, a sum which adds infinitely many numbers. We do not discuss these situations in general in this unit. We say a bit more about how to think of this rule in Definition 29 below.

that these data satisfy the conditions for a probability space. What do you think should be the probability of the interval  $(r, r')$ ?

**Example 4.22.** We continue Example 4.18.

- $S = \{2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\}$  and
- $\mathcal{E} = \mathcal{P}S$

but what is the probability distribution we should use here? Since every subset of  $S$  can be written as a disjoint union of sets containing one element each the second condition for probability distributions tells us that it is sufficient to know the probability for each outcome since, for example

$$\begin{aligned} P\{2, 3, 4, 5\} &= P(\{2\} \cup \{3\} \cup \{4\} \cup \{5\}) \\ &= P\{2\} + P\{3\} + P\{4\} + P\{5\}. \end{aligned}$$

This still leaves us with the question of what  $P\{2\}$ ,  $P\{3\}$ , and so on, should be. If we look at our sample space more closely we find that it in itself can be viewed as a collection of simpler events.

If we look at the outcome ‘the sum of the eyes shown by the two dice is 4’ then we see that this is a complex event: Assume we have a red die and a blue die, then the following combinations will give the sum of four (giving the red die followed by the blue one):

$$\begin{array}{c} \bullet \cdot \\ \text{red} \end{array} \quad \begin{array}{c} \cdot \\ \text{blue} \end{array} \quad \begin{array}{c} \bullet \cdot \\ \text{red} \end{array} \quad \begin{array}{c} \cdot \\ \text{blue} \end{array} \quad \begin{array}{c} \bullet \\ \text{red} \end{array} \quad \begin{array}{c} \cdot \cdot \\ \text{blue} \end{array}.$$

So we might instead decide that our sample space should look different to make the outcomes as simple as possible to make it easier to determine their probabilities.

If we record the result of throwing the two dice simultaneously as a pair

$$(\textcolor{red}{i}, \textcolor{blue}{j}),$$

where the first component  $i$  tells us the value of the red, and  $j$  the value of the blue die. Then our new sample space becomes

$$\{(i, j) \mid 1 \leq i, j \leq 6\}.$$

If we assume that our two dice are both ‘fair’, that is, every number appears with equal probability then the event of throwing, say, a three with the red die will be  $1/6$ , as will be the probability for all the other possible outcomes from 1 to 6. The same is true for the blue die. If we now assume that throwing the red die has no effect on the blue die<sup>10</sup> then the probability of each possible outcome<sup>11</sup>

$$(\textcolor{red}{i}, \textcolor{blue}{j}) \quad \text{is} \quad \frac{1}{6} \cdot \frac{1}{6} = \frac{1}{36}.$$

The outcomes in our previous sample space are now *events in the new space*, and the probability that the sum thrown is 4, for example, (the old event  $\{4\}$ ) is given by the new event

$$\{(1, 3), (2, 2), (3, 1)\},$$

and its probability is the sum of the probabilities for each singleton, that is

$$\begin{aligned} P\{(1, 3), (2, 2), (3, 1)\} &= P\{(1, 3)\} + P\{(2, 2)\} + P\{(3, 1)\} \\ &= \frac{1}{36} + \frac{1}{36} + \frac{1}{36} \\ &= \frac{3}{36} \\ &= \frac{1}{12}. \end{aligned}$$

For completeness' sake we give a full description of both probability spaces. Because the set of events is the powerset of the sample set it is sufficient to give the probability of each outcome. We begin by describing the second probability space in the somewhat boring table below, where the probability for the outcome  $(i, j)$  is the entry in the row labelled  $i$  and the column labelled  $j$ .

$i \setminus j$	1	2	3	4	5	6
1	1/36	1/36	1/36	1/36	1/36	1/36
2	1/36	1/36	1/36	1/36	1/36	1/36
3	1/36	1/36	1/36	1/36	1/36	1/36
4	1/36	1/36	1/36	1/36	1/36	1/36
5	1/36	1/36	1/36	1/36	1/36	1/36
6	1/36	1/36	1/36	1/36	1/36	1/36

The outcome  $k$  from the original space can be thought of as an event in the new space, namely that of

$$\{(i, j) \in \{1, 2, 3, 4, 5, 6\}^2 \mid i + j = k\},$$

and the probability of outcome  $k$  in the original space is equal to the probability of the corresponding event in the new space.

Below we give a table that translates the outcomes from our first sample space to events for the second sample space.

2	3	4	5	6	7	8	9	10	11	12
(1,1)	(1,2)	(1,3)	(1,4)	(1,5)	(1,6)	(2,6)	(3,6)	(4,6)	(5,6)	(6,6)
	(2,1)	(2,2)	(2,3)	(2,4)	(2,5)	(3,5)	(4,5)	(5,5)		
		(3,1)	(3,2)	(3,3)	(3,4)	(4,4)	(5,4)			
			(4,1)	(4,2)	(4,3)	(5,3)	(6,3)			
				(5,1)	(5,2)	(6,2)				
					(6,1)					

Hence the original probability space has a probability distribution determined by the following table:

2	3	4	5	6	7	8	9	10	11	12
$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

There is a third sample space one could use here: As outcomes use an ordered list  $[i, j]$  of numbers, to mean ‘the die with the lower number shows  $i$  and the die with the higher number shows  $j$ ’. The whole sample space is then

$$\{[i, j] \mid i, j \in \{1, 2, 3, 4, 5, 6\}, i \leq j\},$$

and we give the probabilities for those outcomes below. We give the lower number in the set to determine the row and the higher number for the column.

$i \setminus j$	1	2	3	4	5	6
1	$1/36$	$2/36$	$2/36$	$2/36$	$2/36$	$2/36$
2		$1/36$	$2/36$	$2/36$	$2/36$	$2/36$
3			$1/36$	$2/36$	$2/36$	$2/36$
4				$1/36$	$2/36$	$2/36$
5					$1/36$	$2/36$
6						$1/36$

In summary, we have given here three probability spaces that describe the given situation, with different underlying sample spaces.

We learn from this example that there may be more than one suitable sample space, and that by making the possible outcomes as simple as possible we may find their probabilities easier to determine. If the sample space is finite then calculating the probability of any event amounts to adding up the probabilities for the individual outcomes.

**Exercise 58.** Assume you have two dice, one red, one blue, that show a number from 1 to 3 with equal probability. You wish to calculate the probabilities for the numbers that can occur when deducting the number shown by the blue die from that of the red one. For example, if the red die shows 2 and the blue die shows 3, the number to be calculated is  $-1$ .

Give two probability spaces that describe this situation and describe how to calculate the probabilities asked for in each case. *Hint: If you are finding this difficult then read on to the next section which contains more worked examples.*

So picking a suitable sample space for the problem that one tries to solve is important. It’s not unusual to have a number of candidates, but some of them will be easier to describe correctly than others.

#### 4.2.3 Discrete probability distributions

The above example suggests the idea of the following result. It tells you that if you have a finite sample space then describing a probability space for

<sup>10</sup>This property is known as *independence*, see Definition 29.

<sup>11</sup>Compare Example 4.75.

it can be quite easy.

### Proposition 4.2

Let  $S$  be a finite set.

- (i) If for each  $s \in S$  we have the probability  $ps \in [0, 1]$  that  $s$  occurs, and the sum of these probabilities is 1, then a probability space is given by

- the sample space is  $S$ ,
- the set of events is the power set of  $S$ ,  $\mathcal{P}S$ ,
- the probability distribution  $P$  is given by

$$\{s_1, s_2, \dots, s_n\} \longmapsto ps_1 + ps_2 + \dots + ps_n,$$

where  $n \in \mathbb{N}$  and  $s_1, s_2, \dots, s_n \in S$ , which means that for every subset  $E$  of  $S$ , the probability of  $E$  is given by

$$PE = \sum_{s \in E} ps.$$

Moreover this is the only probability space where

- all sets of the form  $\{s\}$  are events and
- the probability of the event  $\{s\}$  occurring is  $ps$ .

- (ii) If  $(S, \mathcal{E}, P)$  is a probability space with the property that for  $s \in S$ ,  $\{s\} \in \mathcal{E}$  then

- $\mathcal{E} = \mathcal{P}S$  and
- we may read off the probability  $ps$  that any given outcome  $s$  occurs by considering  $P\{s\}$ .

**Proof.** (i) We have already stated that the powerset of any set is a  $\sigma$ -algebra, so it is sufficient to check that the probability distribution we selected satisfies the required properties.

- We note that the way we have defined the probability distribution, the probability of  $S$  is the sum of the probabilities for the outcomes, and the assumption explicitly stated is that this adds to 1, so  $P(S) = 1$ .
- If we have pairwise disjoint events  $E_i$  for  $i \in \mathbb{N}$  then the probability of

$$\bigcup_{i \in \mathbb{N}} E_i$$

is the sum of all the probabilities of elements in this set. But if the  $E_i$  are pairwise disjoint then each element of  $\bigcup_{i \in \mathbb{N}} E_i$  occurs

in exactly one of the  $E_i$ , and so

$$\begin{aligned} P(\bigcup_{i \in \mathbb{N}} E_i) &= \sum_{s \in \bigcup_{i \in \mathbb{N}} E_i} Ps && \text{def } P \\ &= \sum_{i \in I} \sum_{s \in E_i} Ps && E_i \text{ pairwise disjoint} \\ &= \sum_{i \in \mathbb{N}} PE_i && \text{def } P.. \end{aligned}$$

(ii) The second statement really has only one property that we need to prove, namely that  $\mathcal{P}S$  is the set of events for the given space.

But if  $S$  is finite, and all sets of the form  $\{s\}$  are events, then for an arbitrary subset  $S'$  of  $S$  we can list the elements, for example

$$S' = \{s_1, s_2, \dots, s_n\},$$

and by setting

$$E_i = \begin{cases} \{s_i\} & \text{for } 1 \leq i \leq n \\ \emptyset & \text{else} \end{cases}$$

we have events  $E_i$  for  $i \in \mathbb{N}$  with the property that

$$S' = \bigcup_{i \in \mathbb{N}} E_i,$$

and since  $\mathcal{E}$  is a  $\sigma$ -algebra we know that  $S' \in \mathcal{E}$ . Hence every subset of  $S$  is an event, and so  $\mathcal{E} = \mathcal{P}S$ .

### Tip

This proposition says that in order to describe a probability space with a *finite* sample space  $S$  all we have to do is to

- describe the sample space  $S$ ;
- say the  $\sigma$ -algebra  $\mathcal{E}$  is  $\mathcal{P}S$ ;
- give the probability for each outcome from  $S$  and state that the probability for each event is given by the sum of the probabilities of its elements.

**Example 4.23.** Throwing a single die can be described by the probability space given by

- $S = \{1, 2, 3, 4, 5, 6\}$ ;
- $\mathcal{E} = \mathcal{P}S$ ;
- the probability distribution assigns the probability of  $1/6$  to each outcome; the probability of an event is given by the sum of the probabilities of its elements.

In practice we often leave out the last statement, or shorten it.

**Example 4.24.** Tossing a coin can be modelled by a probability space with

- sample set  $S = \{H, T\}$ ,
- set of events  $\mathcal{E} = \mathcal{P}S$  and
- a probability distribution determined by the fact that each outcome occurs with probability  $1/2$ .

**Example 4.25.** The probability space underlying Exercise 50 has as its underlying sample space the set

$$\{Q\spadesuit, A\spadesuit, Q\heartsuit, A\heartsuit\} \times \{Q\spadesuit, A\spadesuit, Q\heartsuit, A\heartsuit\},$$

and the probability for each outcome is  $1/16$ . The probability distribution is derived from this in the usual way.

### Proposition 4.3

If we have a sample set

$$S = \{s_i \mid i \in \mathbb{N}\},$$

then a probability space is uniquely determined by assigning to each element  $s$  of  $S$  a probability  $ps$  in  $[0, 1]$  such that

$$\sum_{i \in \mathbb{N}} ps_i = 1/$$

**Optional Exercise 12.** Can you take the proof of Proposition 4.2 and turn it into one for Proposition 4.3?

**Example 4.26.** Assume we toss a coin until we see head for the first time, compare Exercise 56. To describe a probability space for this situation we pick the sample set

$$\{1, 2, 3, \dots\} = \mathbb{N} \setminus \{0\},$$

which tells us how many times we tossed the coin until heads appeared.

The probability for each of these outcomes is given in the following table.

1	2	3	4	5	6	$\dots$
$\frac{1}{2}$	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{1}{16}$	$\frac{1}{32}$	$\frac{1}{64}$	$\dots$

which means that

$$pi = \frac{1}{2^i}.$$

It is the case (but a proof is beyond the scope of this unit) that

$$\sum_{i \in \mathbb{N}} ps_i = \sum_{i \in \mathbb{N}} \frac{1}{2^i} = 1,$$

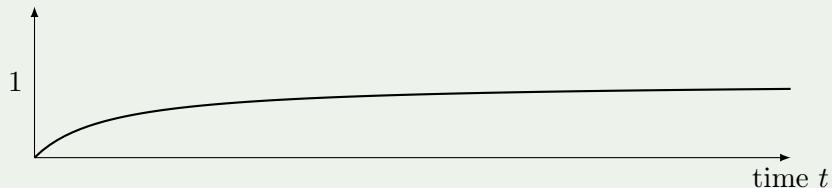

so this distribution satisfies the requirements from Proposition 56.

**CExercise 59.** Find probability spaces to describe the various situations from Exercises 49 (a)–(l) and Exercises 54 to 56. It is fine to describe these in text where you find it difficult to use set and function notation.

#### 4.2.4 Continuous probability distributions

Sometimes it is more appropriate to have a continuous description of a problem. This is often the case when we are plotting events over time. Note that we can only talk about ‘continuous behaviour’ if we may use a sub-interval of the real numbers to describe the outcome of our probability space. See Definition 33 for a formal definition of what we mean by the discrete versus continuous case here.

**Example 4.27.** The following curve of a function  $f$ , might describe<sup>12</sup> the probability that a piece of hardware will have failed by time  $t$ .

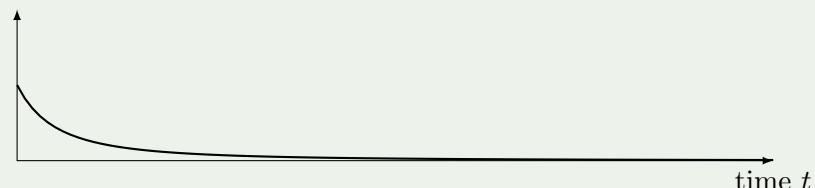

As time progresses the probability of the component having failed approaches 1. But how do we turn this kind of function into a probability space?

We need to identify a set of events, and we need to be able to derive the probability of that event. What we know is how to read off a probability of the our device will have failed in the time interval from 0 to  $t$ : That probability is given by  $ft$ .

This is, in fact, known as a *cumulative probability distribution*: As time progresses the probability becomes higher and higher because the time interval covered becomes bigger and bigger.

In order to give a probability space we need the *probability density function*, which tells us the probability of the device failing at time  $t$ . For the function above this is given by the function  $g$  plotted below.

The relationship between the two functions is that for all  $t$  in  $\mathbb{R}^+$  we have

$$ft = \int_{x=0}^t gxdx.$$

The reason for this becomes clear in Section 4.4.6.

It is possible to give a probability space based on the real numbers, but the precise description is quite complicated. For completeness' sake we note the following two facts.

### Fact 9

There is a  $\sigma$ -algebra  $\mathcal{E}_B$  on the set of real numbers  $\mathbb{R}$  known as the *Borel  $\sigma$ -algebra* with the property that

- all intervals  $[r, r']$ , where  $r, r' \in \mathbb{R}$ , are elements of  $\mathcal{E}_B$ .

Let  $I$  be any interval in  $\mathbb{R}$ . Then we can restrict the Borel  $\sigma$ -algebra to this interval to obtain another  $\sigma$ -algebra  $\mathcal{E}_B^I$  by setting

$$\mathcal{E}_B^I = \{E \cap I \mid E \in \mathcal{E}_B\}.$$

### Fact 10

Let  $[s, s']$  be an interval in  $\mathbb{R}$  with  $s < s'$ . Then there is a probability distribution<sup>13</sup>  $P$  to give a probability space  $([s, s'], \mathcal{E}_B^{[s, s']}, P)$  with the property that for any interval  $[r, r']$  in  $[s, s']$  we have

$$P[r, r'] = \frac{r' - r}{s' - s}.$$

The probability space for Example 4.27 is then given by  $(\mathbb{R}^+, \mathcal{E}_B^+, P_B)$  where

- $\mathcal{E}_B^{\mathbb{R}^+}$  is the restriction of the Borel  $\sigma$ -algebra from Fact 9 and
- the probability distribution is determined by the fact that it satisfies , for all  $r \leq r'$  in  $\mathbb{R}^+$ ,

$$P[r, r'] = \int_r^{r'} gxdx.$$

Whenever you are asked to define a continuous probability space you may assume that

- you may use the Borel  $\sigma$ -algebra adjusted as in the above example and
- we can calculate a probability distribution for this  $\sigma$ -algebra from any probability density function (see the Definition below).

So it is sufficient for you to give a probability density function in this case.

---

<sup>12</sup>One would hope that for a real piece of hardware the probability rises more slowly at first!

<sup>13</sup>This is based on the *Borel measure*.

### Definition 28: probability density function

Let  $I$  be a sub-interval of the real numbers. A **probability density function** for  $I$  is given by a function

$$g: I \longrightarrow \mathbb{R}^+$$

with the property that

$$\int_I g x dx = 1,$$

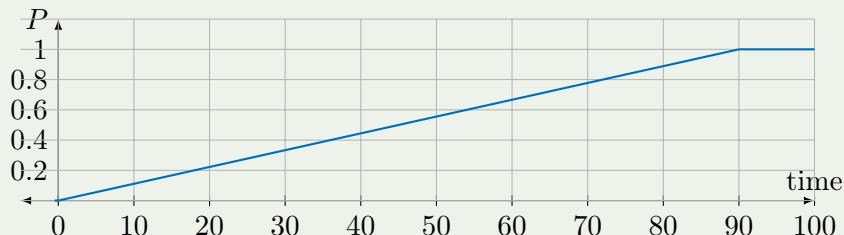

and such that

$$\int_r^{r'} g x dx$$

exists for all  $r \leq r'$  in  $I$ .

**Example 4.28.** Assume you have travelled to Yellowstone National Park and want to see the famous geyser ‘Old Regular’ erupt. You know<sup>14</sup> that it does so every ninety minutes. You are pressed for time, and when you arrive you know you can only stay for twenty minutes. What is the probability that you will see the geyser erupt in that time?

We can describe this situation using the fact that we know that as time goes from 0 to 90 minutes the probability of seeing the geyser erupt rises steadily towards 1. This means that the cumulative distribution function  $f$  looks as follows.

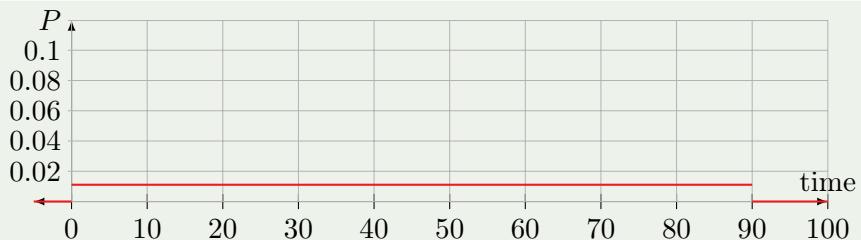

We are looking for a function  $g$  (the probability density function for the cumulative mass function  $f$  in the graph above) on the interval from 0 to 90 minutes with property that for all  $0 \leq x \leq 90$  we have

$$f(x) = \int_0^{90} g x dx.$$

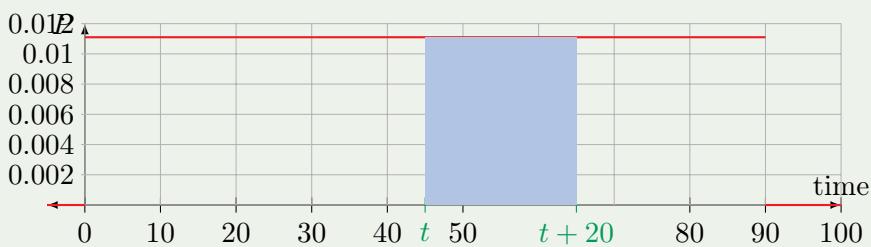

Solving this tells us that  $g$  is *constant*, and it only remains to calculate the constant which comes from the constraint that the integral over  $g$  from 0 to 90 must be 1. Assume that  $g x = c$  for all  $0 \leq x \leq 90$ . Then we need

$$1 = \int_0^{90} c dx = c \cdot 90,$$

so we must have  $0 = 1/90$ .

We can see that it does not matter when exactly you arrive - the distribution is uniform. So if you arrive at time  $t$  and stay for 20 minutes then the probability that you will see the geyser erupt is given by the integral from  $t$  to  $t + 20$  over the function  $g$ , which is given by the shaded area.

This means that the desired probability is

$$\int_{45}^{65} \frac{1}{90} dx = \frac{1}{90}(65 - 45) = \frac{20}{90} = 0.\bar{2},$$

so the probability is just over 20%.

**EExercise 60.** Describe probability density functions for the following situations:

- (a) It is known that the probability of a component having failed rises from 0 to 1 over the time interval from 0 to 1 unit of time at a constant rate.
- (b) A bacterium lives for two hours. It is known that its chance of dying in any 10 minute interval during those two hours is the same. What do you think the probability density function should be?
- (c) Assume you have an animal which lives in a one dimensional space described by the real line  $\mathbb{R}$ . Assume that its den is at 0, and that the probability of the animal being at a particular spot  $r$  falls at a constant rate and reaches 0 when the animal is one unit away from its den. Give a probability density function for this situation. What does the corresponding cumulative probability distribution look like in this case?

---

<sup>14</sup>The most famous geyser that actually exists there, known as Old Faithful, does not erupt as regularly as my imaginary example.

(d) Try to extend the previous part to an animal that lives in a two dimensional space described by the real plane,  $\mathbb{R} \times \mathbb{R}$ .

#### 4.2.5 Consequences from Kolmogorov's axioms

The axioms from Definition 27 have a number of consequences that are useful to know about.

We look at them one by one here and summarize them in a table at the end of the section.

##### The empty set

- The empty set  $\emptyset$  is an event: Definition 27 says that if  $E$  is an event then so is  $S \setminus E$ . Since  $S$  is an event this means that  $S \setminus S = \emptyset$  is an event.
- Now that we know that  $\emptyset$  is an event we may calculate its probability as follows.

$$\begin{aligned} 1 &= PS && \text{Definition 27} \\ &= P(S \cup \emptyset) && S \cup \emptyset = S \\ &= PS + P\emptyset && S \text{ and } \emptyset \text{ disjoint, Def 27} \\ &= 1 + P\emptyset && PS = 1 \end{aligned}$$

and so

$$P\emptyset = 1 - 1 = 0.$$

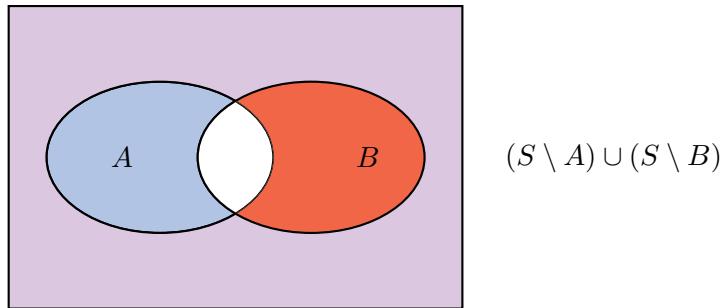

##### Intersection

If we know that  $A$  and  $B$  are events, what can we say about  $A \cap B$ ? We note that there is nothing in the axioms that talks about intersections. But it turns out that we can use the axioms to argue that the intersection is an event.

We calculate<sup>15</sup>

$$A \cap B = S \setminus ((S \setminus A) \cup (S \setminus B)).$$

In the following diagram  $(S \setminus A) \cup (S \setminus B)$  is the coloured area, and the white part is its complement, that is the desired set.

---

<sup>15</sup>See Exercise 6.

Since the complement of an event is an event we know that  $S \setminus A$  and  $S \setminus B$  are events, and we have seen that the union of a finite number of events is another event.<sup>16</sup>

In general there is no way of calculating the probability of  $A \cap B$  from the probabilities of  $A$  and  $B$ . When the two events are *independent* then this situation changes, see Definition 29.

We may summarize this as follows:

- If  $A$  and  $B$  are events then so is their intersection  $A \cap B$ .
- There is no general way of calculating the probability of  $A \cap B$  from those of  $A$  and  $B$ .

### Complement and relative complement

We begin by looking at the complement of a set.

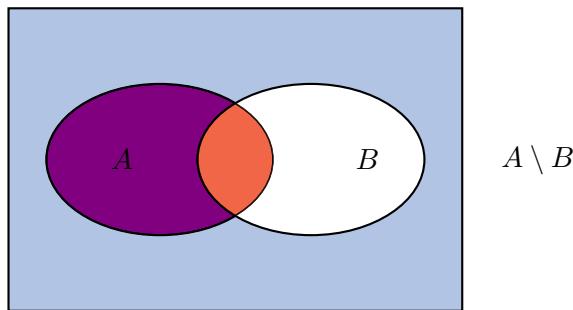

- If  $A$  is an event then we know that its complement  $S \setminus A$  is also an event.
- We also know that a set and its complement are disjoint sets whose union is  $S$ . Hence we know that

$$\begin{aligned} 1 &= PS && \text{Definition 27} \\ &= P(A \cup (S \setminus A)) && S = A \cup (S \setminus A) \\ &= PA + P(S \setminus A) && A, S \setminus A \text{ disjoint, Def 27} \end{aligned}$$

and so<sup>17</sup>

$$P(S \setminus A) = 1 - PA.$$

More generally, assume we have events  $A$  and  $B$ . The picture shows  $A$  in red and  $S \setminus B$  in pale blue, with violet giving the overlap. The set whose probability we wish to compute is that overlap, the darkest set in the following picture.

We would like to argue that  $A \setminus B$  is an event. We note that the definition of a  $\sigma$ -algebra tells us that since

$$S \setminus A \quad \text{and} \quad B$$

---

<sup>16</sup>Note that we can also show that the countable intersection of events is an event by generalizing this idea.

<sup>17</sup>Some people write this as  $P(\neg A) = 1 - PA$  or  $P(A^C) = 1 - PA$ , but we do not use that notation here.

are events we may form another event in the form of

$$S \setminus A) \cup B$$

and so we get an event when forming (compare Exercise 6 for the trick we employ here)

$$S \setminus ((S \setminus A) \cup B) = A \cap (S \setminus A) = A \setminus B.$$

is also an event. Further we can split this event into disjoint parts by forming

$$A = (A \setminus B) \cup (A \cap B),$$

and so (compare Exercise 57)

$$\begin{aligned} PA &= P((A \setminus B) \cap (A \cap B)) & A &= (A \setminus B) \cup (A \cap B) \\ &= P(A \setminus B) + P(A \cap B) & (A \setminus B), A \cap B \text{ disjoint, Def 27}, \end{aligned}$$

which gives us

$$P(A \setminus B) = PA - P(A \cap B).$$

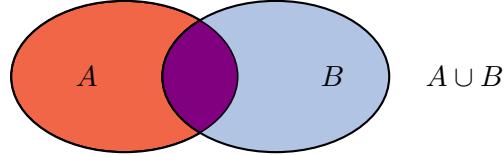

We may summarize this by saying the following.

- If  $A$  and  $B$  are events then so is  $A \setminus B$ .
- We have  $P(A \setminus B) = PA - P(A \cap B)$ .

## Union

If we want to calculate the probability of the union of two events then in order to apply Kolmogorov's axiom we must write it as the union of disjoint events.

The Venn diagram for two non-disjoint set looks like this:

We can see that if we want to write  $A \cup B$  as a disjoint union we have to pick for example the red and violet regions, which make up  $A$ , and the blue region, which is  $B \setminus A$ , and write

$$A \cup B = A \cup (B \setminus A).$$

With the result for the relative complement we get

$$\begin{aligned} P(A \cup B) &= P(A \cup (B \setminus A)) & A \cup B &= A \cup (B \setminus A) \\ &= PA + P(B \setminus A) & A, B \setminus A \text{ disjoint, Def 27} \\ &= PA + PB - P(A \cap B) & P(B \setminus A) &= PB - P(A \cap B). \end{aligned}$$

In summary we can say that

- if  $A$  and  $B$  are events then so is  $A \cup B$  and
- we have  $P(A \cup B) = PA + PB - P(A \cap B)$ .

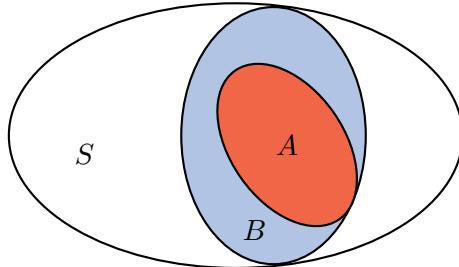

Note that if  $A$  and  $B$  do not overlap then

$$A \cap B = \emptyset \quad \text{and} \quad P(A \cup B) = PA + PB$$

as expected.

## Order preservation

Assume we have two events  $A$  and  $B$  with the property that  $A$  is a subset of  $B$ .

What can we say about the probabilities of  $A$  and  $B$ ? Certainly we can see that  $B$  is the disjoint union of  $A$  and  $B \setminus A$ , and so

$$PB = PA + P(B \setminus A).$$

Since the probability of  $B \setminus A$  is greater than or equal to 0 we must have

$$PA \leq PB.$$

## Summary

We give all the rules derived above. Let  $(S, \mathcal{A}, P)$  be a probability space, and let  $A$  and  $B$  be events. Then the following rules hold.

$$\begin{aligned} PS &= 1 & P\emptyset &= 0 \\ P(S \setminus A) &= 1 - PA & P(A \setminus B) &= PA - P(A \cap B) \\ P(A \cup B) &= PA + PB - P(A \cap B) \\ A \subseteq B \text{ implies } PA &\leq PB. \end{aligned}$$

It may be worth pointing out that these conditions hold for all probability spaces, in particular they also hold for the case where we are given a probability density function. The first two conditions are trivially true, and the others are standard properties of integrals.

**Optional Exercise 13.** Convince yourself that the various equalities hold if the probability distribution is given by a probability density function. You may want to draw some pictures for this purpose.

### 4.2.6 Kolmogorov's axioms revisited

How should we think of the Kolmogorov axioms? The definition of a  $\sigma$ -algebra is something of a formality that ensures that the sets for which we have a probability (namely the *events*) allow us to carry out operations on them.

We may think of the probability distribution as a way of splitting the probability of 1 (which applies to the whole set  $S$ ) into parts (namely those

subsets of  $S$  which are events). If  $S$  is finite then we only have to know how the probability of 1 is split among the elements of  $S$ , and then we can assign a probability to each subset of  $S$  by adding up all the probabilities of its elements.

This becomes significantly more complicated if the set is infinite.

#### Proposition 4.4

If  $S$  is an infinite set then there is no probability distribution which assigns the same probability to each event  $\{s\}$  of  $S$ .

The simplest infinite set we have met is the set of natural numbers  $\mathbb{N}$ . If we had a probability distribution on  $\mathbb{N}$  which assigned a fixed probability  $r \in [0, 1]$  to each element then it would have to be the case that the sum of all these probabilities is 1, that is

$$\sum_{i \in \mathbb{N}} r = \sum_{i \in \mathbb{N}} P\{i\} = 1$$

and there is no real number  $r$  with that property.

Note that the probability space defined in Fact 10 is uniform in that it assigns the same probability to intervals of the same length. So it is possible to distribute probability uniformly in two cases:

- the sample set  $S$  is finite, in which case we may assign the same probability,  $1/|S|$ , to each outcome or
- the sample set  $S$  is an interval in  $\mathbb{R}$ , in which case the probability of any one outcome is 0, but intervals have non-0 probabilities which is determined by their length.

However, there is no way of taking *all* the subsets of  $\mathbb{R}$  (or any interval  $I$ ), and turning that into a probability space.

#### Proposition 4.5

Let  $I$  be an interval on the real line. There is no probability distribution  $P$  with the property that,  $(I, \mathcal{P}I, P)$  is a probability space which maps intervals of the same size to the same probability.

This proposition explains why we cannot have a simpler definition of probability space, where the set of events is always the powerset of the sample space.

### 4.3 Conditional probabilities and independence

One of the questions that appears frequently in the context of probability theory is that of how information can be used. In other words, can we say something more specific if we already know something about the situation at hand. This section is concerned with describing how we may use the axioms of probability to make this work.

### 4.3.1 Independence of events

Kolmogorov's axioms are not strong enough to allow us to calculate the probability of

$$A \cap B$$

if we know the probabilities of  $A$  and  $B$ . This section sheds some light on the question why there cannot be a general formula that does this.

When we throw two dice, one after the other, or when we throw a coin repeatedly, we are used to a convenient way of calculating the corresponding probabilities for the outcomes.

**Example 4.29.** Assume we record the outcome of a coin toss with  $H$  for head and  $T$  for tails. We assume the coin is fair and so the probability for each is  $1/2$ . If we toss the coin twice then the possible outcomes are  $HH$ ,  $HT$ ,  $TH$  and  $TT$  and the probability for each is  $1/4$ . We may calculate the probability  $HT$ , that is the first coin toss  $C1$  coming up  $H$ , and the second,  $C2$ ,  $T$  as follows.

$$P((C1 = H) \cap (C2 = T)) = P(C1 = H) \cdot P(C2 = T) = 1/2 \cdot 1/2 = 1/4$$

But it is not safe to assume that for general events  $A$  and  $B$  we have that the probability of  $A \cap B$  can be calculated by multiplying the probabilities of  $A$  and  $B$ , see Example 4.30.

#### Definition 29: independent events

Given a probability space  $(S, \mathcal{E}, P)$  we say that two events  $A$  and  $B$  are **independent** if and only if

$$P(A \cap B) = PA \cdot PB.$$

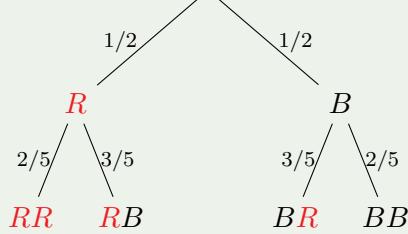

What we mean by ‘independent’ here is that neither event has an effect on the other. We assume that when we throw a coin multiple times then the outcome of one toss has no effect on the outcome of the next, and similar for dice. We look at this issue again in Section 4.4.5 when we have random processes which are more easily described. In particular we talk about independence for processes with a continuous probability distribution.

**Example 4.30.** Let us look at a situation where we have events which are not independent. In Example 4.13 we discussed pulling socks from a drawer. We assume that we have a drawer with three red and three black socks from which we draw one sock at a time without looking inside. If you pick a red sock on the first draw, then the probability of finding a red sock on the second draw is changed.

The probability of drawing a red sock on the first attempt is

$$P(D_1 = R) = 1/2,$$

but what about the probability of drawing a red sock on the second attempt? Again it is best if we look at the tree that shows us how the draw progresses.

We can see that the probability of drawing a red sock on the second attempt is

$$P(D_2 = \text{R}) = \frac{1}{2} \cdot \frac{2}{5} + \frac{1}{2} \cdot \frac{3}{5} = \frac{2+3}{10} = \frac{1}{2}.$$

But we can also see from the tree that

$$P((D_1 = \text{R}) \cap (D_2 = \text{R})) = \frac{1}{2} \cdot \frac{2}{5} = \frac{1}{5},$$

which is not equal to

$$P(D_1 = \text{R}) \cdot P(D_2 = \text{R}) = \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{4},$$

so (very much expectedly) the two events are not independent.

**Example 4.31.** A more serious example is as follows. SIDS, or ‘Sudden Infant Death Syndrome’ refers to what is also known as ‘cot death’—young children die for no reason that can be ascertained. In 1999 an ‘expert witness’ told the court that the approximate probability of a child of an affluent family dying that way is one in 8500. Since two children in the same family had died this way, the expert argued, the probability was one in 73 million that this would occur, and a jury convicted a young woman called Sally Clark of the murder of her two sons, based largely on this assessment.

The conviction was originally upheld on appeal, but overturned on a second appeal a few years later. While Clark was released after three years in prison she later suffered from depression and died from alcohol poisoning a few years after that.

What was wrong with the expert’s opinion? The number of 1 in 73 million came from multiplying 8500 with itself (although 72 million would have been more accurate), that is, arguing that if the probability of one child dying in this way is

$$\frac{1}{8500},$$

then the probability of two children dying in this way is

$$\frac{1}{8500} \cdot \frac{1}{8500}.$$

But we may only multiply the two probabilities if the two events are independent, that is, if the death of a second child cannot possibly be related to the death of the first one. This explicitly assumes that there is no genetic or environmental component to SIDS, or that there may

not be other circumstances which makes a second death in the same family more likely. Since then data have been studied that show that the assumption of the independence of two occurrences appears to be wrong.

While there were other issues with the original conviction it is shocking that such evidence could be given by a medical expert without anybody realizing there was a fallacy involved. I hope that this example illustrates why it is important to be clear of the assumptions one makes, and to check whether these can be justified.

Note that if we know that two events are independent then we may derive from that the Independence of other events.

**Example 4.32.** If  $A$  and  $B$  are independent events in a probability space with sample set  $S$  then  $A$  and  $S \setminus B$  are also independent.

To prove this we have work out the probability of the intersection of the two events. We calculate

$$\begin{aligned} P(A \cap (S \setminus B)) &= P(A \setminus B) & A \setminus B = A \cap (S \setminus B) \\ &= PA - P(A \cap B) & \text{rules on page } 150 \\ &= PA - PA \cdot PB & A \text{ and } B \text{ independent} \\ &= PA(1 - PB) & \text{arithmetic} \\ &= PA \cdot P(S \setminus B) & P(S \setminus B) = 1 - PB \end{aligned}$$

which establishes that the two given events are indeed independent.

**Exercise 61.** Show that if  $A$  and  $B$  are independent then so are  $S \setminus A$  and  $S \setminus B$ .

A common fallacy is to assume that two events being independent has something to do with them being disjoint, that is, there not being an outcome that belongs to both. The following exercise discusses why this is far from the truth.

**Exercise 62.** Assume that you have a probability space with two events  $A$  and  $B$  such that  $A$  and  $B$  are disjoint, that is  $A \cap B = \emptyset$ . What can you say about  $PA$ ,  $PB$  and  $P(A \cap B)$  under the circumstances? What can you say if you are told that  $A$  and  $B$  are independent?

Give a sufficient and necessary condition that two disjoint events are independent.

### 4.3.2 Conditional information

For example, if I have to guess the colour of somebody's eyes, but I already know something about the colour of their hair then I can use that information to guide my choice.

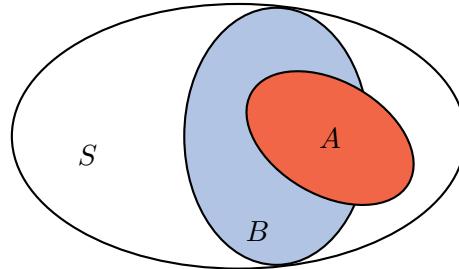

**Example 4.33.** Let us assume we have a particular part of the population where 56% have dark hair and brown eyes, 14% have dark hair and blue eyes, 3% have fair hair and brown eyes and 27% have fair hair and blue eyes.

If I know a person has been randomly picked from the population, and I have to guess the colour of their eyes, what should I say to have the best chance of being right?

	brown eyes	blue eyes
dark haired	56%	14%
fair haired	3%	27%

We can see from the numbers given that we are better off guessing brown (lacking additional information). But what if we can see that the person in question has fair hair? In that case we are better off guessing blue. What is the appropriate way of expressing these probabilities? This example is continued below.

What we are doing here can be pictured by assuming that in the sample space  $S$  we have two sets,  $A$  and  $B$ .

We are interested in the probability of  $A$  (say blue eye colour) already knowing that  $B$  holds (say fair hair). In the picture above this means the probability that we are in the blue set  $A$ , provided we already know that we are in the red set  $B$ .

What we are doing effectively is to change the sample space  $S$  to  $B$ , and we want to know the probability of  $A \cap B$ .

#### Proposition 4.6

If  $(S, \mathcal{E}, P)$  is a probability space and  $B$  an event with non-zero probability then a probability space is given by the following data:

- sample set  $B$ ,
- set of events  $\{B \cap E \mid E \in \mathcal{E}\}$ ,
- probability distribution  $P'$  defined by

$$B \cap E \longmapsto \frac{P(B \cap E)}{PB} .$$

We can think of the new space as a restriction of the old space with sample set  $S$  to a new space with sample set  $B$ , where we have redistributed

the probability entirely to the set  $B$ , and adjusted all the other probabilities accordingly.

**Optional Exercise 14.** Define a probability space that is an alternative to the one given in Proposition 4.6. Again assume that you have a probability space  $(S, \mathcal{E}, P)$  and a subset  $B$  of  $S$  with non-zero probability. Use

- sample set  $S$ ,
- set of events:  $\mathcal{E}$ ,
- a probability density function that assigns to every event of the form  $B \cap E$ , where  $E \in \mathcal{E}$ , the same probability as the function given in said proposition.

**Optional Exercise 15.** Show that the new set of events in Proposition 4.6 is a  $\sigma$ -algebra.

**Exercise 63.** For the probability distribution  $P'$  from Proposition 4.6 carry out the following:

- (a) Calculate  $P'B$ .
- (b) For  $A \subseteq B$  calculate  $P'A$ .
- (c) Show that  $P'$  is a probability distribution.

### Definition 30: conditional probability

Let  $(S, \mathcal{E}, P)$  be a probability space, and let  $A$  and  $B$  be events, where  $B$  has a non-zero probability. We say that the **conditional probability of  $A$  given  $B$**  is given as

$$P(A | B) = \frac{P(A \cap B)}{PB}.$$

It is the probability of the event  $A \cap B$  in the probability space based on the restricted sample set  $B$  given by Proposition 4.6.

Note that if  $PB = 0$  then  $P(A | B)$  is not defined, no matter what  $A$  is.

**Example 4.34.** Continuing Example 4.33 we can see that the probability that a randomly selected person has blue eyes, given that he or she has fair hair, is

$$P(\text{blue eyes} | \text{fair hair}) = \frac{P(\text{blue eyes and fair hair})}{P(\text{fair hair})} = \frac{.27}{.3} = .9.$$

In other words, if I am presented with a randomly selected person whose hair I happen to know to be fair then by guessing their eye colour is blue I have a 90% chance of being correct.

On the other hand, if I can see the person has dark hair, then the

chance that they have brown eyes is

$$P(\text{brown eyes} \mid \text{dark hair}) = \frac{P(\text{brown eyes and dark hair})}{P(\text{dark hair})} = \frac{.56}{.7} = .8.$$

Hence we can use conditional probabilities to take into account additional information we have been given before making a decision.

**Example 4.35.** If we revisit Example 4.14 we can see that what we calculated was the probability that we have the bag  $GG$  given that we have seen a gold coin. According to the above

$$P(GG \mid G) = \frac{P(GG \cap G)}{PG} = \frac{\frac{1}{3}}{\frac{1}{2}} = \frac{2}{3},$$

just as we concluded on our first encounter of this example.

**Example 4.36.** In the Monty Hall problem, Example 4.16, we can think of being shown that there is a booby prize behind one of the doors as adding information. Effectively the show master is asking us: What is the probability that you picked the correct door, knowing that the door I've just shown you is not the correct door? In other words we are interested in the event that

- the price is behind the door the player chose under the condition that
- we were shown the booby prize behind another door.

The probability that the player has chosen the correct door on the first move is  $1/3$ . The probability that the player chose the incorrect door on the first move is  $2/3$ , and that is the probability that the prize is hidden behind the door to which the player can switch.

**EExercise 64.** Assume that  $(S, \mathcal{E}, P)$  is a probability space with events  $A$ ,  $A'$  and  $B$ . Further assume that  $PB \neq 0$ .

- (a) If you know that  $PA \leq PA'$  what can you say about  $P(A \mid B)$  and  $P(A' \mid B)$ ?
- (b) If you know that  $A \cap B = \emptyset$  what can you say about  $P(A \mid B)$ ?
- (c) If you know that  $A \subseteq B$  what can you say about  $P(A \mid B)$ ?
- (d) What is  $P(B \mid B)$ ?
- (e) How do  $P(A \cap B)$  and  $P(A \mid B)$  compare?

In each case justify your answer.

**Exercise 65.** Assume you know a family with two children.

- If you know the family has at least one girl what is the chance that both children are girls?
- If we know that the family's firstborn was a girl, what is the probability that both children are girls?

You may assume that every birth yields a girl and a boy with equal probability.

**CExercise 66.** Go back to the game described in Exercise 50 whose probability space is given in Example 4.25. For this exercise we only look at the original draw, where I draw two cards from the given deck and then drop one of them.

- What is the probability that I have at least one ace after the draw?
- What is the probability that I have two aces after the draw?
- What is the probability that the dropped card is an ace?
- What is the probability that I have the ace of spades  $A\spadesuit$  given that I dropped a queen?
- What is the probability that I have the ace of spades  $A\spadesuit$  given that I dropped an ace?
- What is the probability that the dropped card was a queen given that I have the ace of spades  $A\spadesuit$ ?
- In the original exercise you were asked to calculate the probability that the dropped card was an ace given that I have the ace of spades  $A\spadesuit$ . Express this using conditional probabilities and recalculate the answer.

**Exercise 67.** Assume you have a probability space  $(S, \mathcal{E}, P)$ ,  $A$  and  $B$  are events, and you know the following:

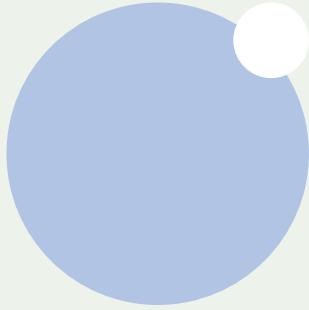

- $PA > 0, PB > 0, P(A \cap B) > 0;$
- $P(A | B) = P(B | A)$  and
- $P(A \cup B) = 1.$

Show that  $PA > 1/2$ . Why is the condition  $P(A \cap B) > 0$  needed?

Note that it does make sense to apply the same ideas in the case where we have a probability density function.

**Example 4.37.** Assume that you have a probability density function describing an animal's location. Further assume that the space in question is centred on the animal's den. Let's assume the animal is a fox, and

that we know that its presence is influenced by the presence of another animal, say a lynx. To make the situation simpler let's say that the fox avoids a circle around the lynx.

If we assume the fox avoids the lynx completely then the fox being in the white area of its range, given there is a lynx at the centre of the white circle, has a probability of 0. But that means the 'mass' of probability that resided in the white area has to go somewhere else (since the overall probability that the fox is somewhere in the area has to be equal to 1)! In the above example we haven't got enough information to decide where it goes.

Further if the situation is more interesting, and the lynx only inhibits, but does not prevent, the foxes presence, the analysis is more complicated. We return to this question in Section 4.4.5 where we restrict how we think of the events that occur, which makes it substantially easier to mathematically describe the situation.

### 4.3.3 Equalities for conditional probabilities

From the definition of the conditional probability we may derive some useful equalities.

Recall that the probability of an event conditional on another is defined only if the latter has a probability greater than 0, but the following equality is true even if the probability is 0:

$$P(A | B) \cdot PB = P(A \cap B),$$

which is also known as the **multiplication law**.

Note that the expression on the left hand side is symmetric in  $A$  and  $B$  since  $A \cap B = B \cap A$  and so we have

$$P(A | B) \cdot PB = P(A \cap B) = P(B | A) \cdot PA.$$

If we like we can use this equality to determine  $P(B | A)$  from  $P(A | B)$ , provided that  $PA \neq 0$ . The equality

$$P(B | A) = \frac{P(A | B) \cdot PB}{PA},$$

is known as **Bayes's Theorem**. It allows us to compute the probability of  $B$  given  $A$ , provided we have the probabilities for  $A$  given  $B$ ,  $A$  and  $B$ .

**Example 4.38.** Revisiting Example 4.34 we have calculated the probability that a fair-haired person has blue eyes. What about the probability that a blue-eyed person has fair hair? Using Bayes's law we have

$$\begin{aligned} P(\text{fair hair} \mid \text{blue eyes}) &= \frac{P(\text{blue eyes} \mid \text{fair hair}) \cdot P(\text{fair hair})}{P(\text{blue eyes})} \\ &= \frac{.9 \cdot .3}{.41} \\ &\approx 65.9\%. \end{aligned}$$

On the other hand the probability that a brown-eyed person has dark hair is

$$\begin{aligned} P(\text{dark hair} \mid \text{brown eyes}) &= \frac{P(\text{brown eyes} \mid \text{dark hair}) \cdot P(\text{dark hair})}{P(\text{brown eyes})} \\ &= \frac{.8 \cdot .7}{.59} \\ &\approx 95\%. \end{aligned}$$

There are further equalities based around conditional probabilities that can be useful in practice. Sometimes the sample space can be split into disjoint events, where we know something about those.

In particular, given an event  $B$  we know that  $B$  and  $S \setminus B$  cover the whole sample space  $S$ . This means we know that (see Exercise 57)

$$A = (A \cap B) \cup (A \cap (S \setminus B)),$$

and this is a disjoint union. By Kolmogorov's axioms given in Definition 27 this implies

$$\begin{aligned} PA &= P((A \cap B) \cup (A \cap (S \setminus B))) \\ &= P(A \cap B) + P(A \cap (S \setminus B)), \end{aligned}$$

and if we use the multiplication law twice, and the properties for probability distributions as needed, then we obtain the following rule.

$$\begin{aligned} PA &= P(A \mid B) \cdot PB + P(A \mid S \setminus B) \cdot P(S \setminus B) \\ &= P(A \mid B) \cdot PB + P(A \mid S \setminus B) \cdot (1 - PB). \end{aligned} \tag{*}$$

This law is a special case of a more general one discussed below. But even this restricted version is useful, for example, when there is a given property and whether or not that property holds has an influence on whether a second property holds.

**Example 4.39.** Assume that motherboards from different suppliers have been stored in such a way that it is no longer possible to tell which motherboard came from which supplier.

Further assume that subsequently it has become clear that those from Supplier 1 ( $S_1$ ) have a 5% chance of being faulty, while that chance is 10% for ones from Supplier 2 ( $S_2$ ). It is known that 70% of supplies in the warehouse came from Supplier 1, and the remainder from Supplier 2. What is the probability that a randomly chosen motherboard is defective?

The rule (\*) from above tells us that

$$\begin{aligned}
 P(\text{defect}) &= P(\text{defect} \mid \text{from S1}) \cdot P(\text{from S1}) + P(\text{defect} \mid \text{from S2}) \cdot P(\text{from S2}) \\
 &= .05 \cdot .7 + .1 \cdot .3 \\
 &= .065.
 \end{aligned}$$

**Example 4.40.** The following is an important case that applies to diagnostic testing in those cases where there is some error (certainly medical tests fall into this category).

Assume a test is being carried out whether some test subject suffers from an undesirable condition. From previous experience it is known that

- if the subject suffers from the condition then with a probability of .99 the test will show this correctly and
- if the subject does not have the condition then with a probability of .95 the test will show this correctly.

We assume that for an arbitrary member of the test population the chance of suffering from the condition is .00001. If a subject tests positive for the condition, what is the probability that they have the condition?

We would like to calculate

$$P(\text{has condition} \mid \text{test positive}).$$

We do not have this data given, but we do have

$$P(\text{test pos} \mid \text{has cond}) \quad \text{and} \quad P(\text{has cond}).$$

If we apply Bayes's theorem we get

$$P(\text{has cond} \mid \text{test pos}) = \frac{P(\text{test pos} \mid \text{has cond}) \cdot P(\text{has cond})}{P(\text{test pos})}.$$

We miss

$$P(\text{test pos}),$$

but we may use rule (\*) above to calculate

$$\begin{aligned}
 P(\text{test pos}) &= P(\text{test pos} \mid \text{has cond}) \cdot P(\text{has cond}) \\
 &\quad + P(\text{test pos} \mid \text{doesn't have cond}) \cdot P(\text{doesn't have cond}) \\
 &= .99 \cdot .00001 + .05 \cdot .99999 \\
 &\approx .05
 \end{aligned}$$

So we may calculate the desired probability as

$$\begin{aligned} P(\text{has cond} \mid \text{test pos}) &= \frac{P(\text{test pos} \mid \text{has cond}) \cdot P(\text{has cond})}{P(\text{test pos})} \\ &\approx \frac{.99 \cdot .00001}{.05} \\ &\approx .0002. \end{aligned}$$

So if we test something, and in the event it tests positive, there's a .02% chance that the subject is ill, would we think this is a good test?

The issue in this example is the extremely low probability that anybody has the condition at all. If we change the numbers and instead assume that the chance that an arbitrary member of the test population has the condition is .1 then we get

$$\begin{aligned} P(\text{test pos}) &= P(\text{test pos} \mid \text{has cond}) \cdot P(\text{has cond}) \\ &\quad + P(\text{test pos} \mid \text{doesn't have cond}) \cdot P(\text{doesn't have cond}) \\ &= .99 \cdot .1 + .05 \cdot .9 \\ &= .144 \end{aligned}$$

and

$$\begin{aligned} P(\text{has cond} \mid \text{test pos}) &= \frac{P(\text{test pos} \mid \text{has cond}) \cdot P(\text{has cond})}{P(\text{test pos})} \\ &= \frac{.99 \cdot .01}{.144} \\ &= .06875. \end{aligned}$$

So in this case the chance that a subject that tests positive has the condition is almost 69%.

In general when you are given the outcome of a test you should ideally also be given enough data to judge what that information means!

Our rule (\*) from above is a special case of a more general law. Instead of splitting the sample space into two disjoint sets,  $B$  and  $S \setminus B$ , we split it into more parts. If  $B_1, B_2, \dots, B_n$  is a collection of pairwise disjoint events such that

$$A \subseteq B_1 \cup B_2 \cup \dots \cup B_n$$

then it is the case (see Exercise 57) that

$$A = (A \cap B_1) \cup (A \cap B_2) \cup \dots \cup (A \cap B_n),$$

and by Kolmogorov's axioms given in Definition 27 we may use the fact that the  $A \cap B_i$ , for  $1 \leq i \leq n$ , are pairwise disjoint (again see Exercise 57) to calculate the probability of  $A$  as

$PA$

$$\begin{aligned} &= P(A \cap B_1) + P(A \cap B_2) + \dots + P(A \cap B_n) && \text{Def} \\ &= P(A \mid B_1)PB_1 + P(A \mid B_2)PB_2 + \dots + P(A \mid B_n)PB_n && \text{mult law} \\ &= \sum_{i=1}^n P(A \mid B_i) \cdot PB_1. \end{aligned}$$

This is sometimes referred to as the **law of total probability**. The way to think about it is that if we split the event  $A$  into disjoint parts of the form

$$A \cap B_i,$$

then the probability of  $A$  can be recovered from the probabilities of the parts, and the probabilities of these parts can be calculated using the multiplication law. Splitting a set into pairwise disjoint parts is also known as *partitioning* the set, and so

The law of total probability is used for a procedure known as Bayesian updating which is discussed in the following section. Examples for the application of this rule can be found there.

**Exercise 68.** Let  $(S, \mathcal{E}, P)$  be a probability space, and assume that  $A$ ,  $B$  and  $C$  are events. Show that the probability of  $A$  holding, given  $B$ , given  $C$ , is the same as the probability that  $A$  holds, given  $B$  and  $C$ . You may assume that all probabilities mentioned are defined.

**Exercise 69.** Prove that the law of total probability holds.

**Exercise 70.** Assume that you have found the following statistical facts about your favourite football team:

- If they score the first goal they win the game with a probability of .7.
- If the other team scores the first goal your team has a probability of .35 of winning the game.
- If your team scores then the probability that the game is a draw is .1.

You have further worked out that in all the matches your team has played, in 55% of all games they have scored, and in 40% of those they have scored first. What is the probability that your team wins a randomly picked game?

After further analysis you have worked out that they lose 80% of all games in which they haven't scored. What is the probability that a randomly picked game your team is involved in is a draw?

**Exercise 71.** One of your friend claims she has an unfair coin that shows heads 75% of the time. She gives you a coin, but you can't tell whether it's that one or a fair version.

You toss the coin three times and get  $HHT$ . What is the probability that the coin you were given is the unfair one?

**Exercise 72.** Assume you have an unfair coin that shows heads with probability  $p \in (0, 1]$ . You toss the coin until heads appears for the first time. Show that the probability that this happens after an even number of tosses is

$$\frac{1-p}{2-p}.$$

*This is a tricky exercise. It depends on cleverly choosing events, and using the law of total probability.*

**Exercise 73.** Consider the following situation: Over a channel bits are transmitted. The chance that a bit is incorrectly received is  $p$ . From observing previous traffic it is known that the ratio of bits of value 1 to bits of value 0 is 4 to 3.

If the sequence 011 is observed what is the probability that this was transmitted?

#### 4.3.4 Bayesian updating

In AI it is customary to model the uncertainty regarding a specific situation by keeping probabilities for each of the possible scenarios. As more information becomes available, for example through carrying out controlled experiments, those probabilities are updated to better reflect what is now known about the given situation. This is a way of implementing machine learning. It is also frequently used in spam detection software.

In this section we look at how probabilities should be updated.

**Example 4.41.** Assume you are given a bag with three socks in it. You are told that every sock in the bag are either red or black. You are asked to guess how many red socks are in the bag. There are four cases:

$$\{0, 1, 2, 3\}.$$

We model this situation by assigning probabilities to the four. At the beginning we know nothing, and so it makes sense to assign the same probability to every one of these. Our first attempt at modelling the situation is to set the following probabilities.

Original distribution	$P$	0	1	2	3
		1/4	1/4	1/4	1/4

This expresses the fact that nothing is known at this stage. Assume somebody reaches into the bag and draws a red sock which they hold up before returning it to the bag. Now we have learned something we didn't know before: there is at least one red sock in the bag. This surely means that we should set  $P_0$  to 0, but is this all we can do?

The idea is that we should update *all* our probabilities based on this information. The probability  $P(i)$  that we have  $i$  red socks in the bag should become

$$P(i | R),$$

that is, it should be the probability that there are  $i$  red socks *given that the drawn sock was red*. Bayes's Theorem helps us to calculate this number since it tells us that

$$P(i \mid R) = \frac{P(R \mid i) \cdot P(i)}{P(R)}.$$

Let us consider the various probabilities that occur in this expression:

- $P(R \mid i)$ . This is the probability that a red sock is drawn, given the total number of red socks. This is known, and it is given by the following table:

$i$	0	1	2	3
$P(R \mid i)$	0	$1/3$	$2/3$	1

So if the number of red socks is  $i$  then the probability of  $P(R \mid i)$  is  $i/3$ .

- $P(i)$ . We don't know how many red socks there are in the bag, but we are developing an estimated guess for the probability, and that is what we are going to use. So where this appears we use the probabilities provided by the first table, our original distribution.
- $P(R)$ . This is the the probability that the first sock drawn is red, *independent from how many red socks there are*. It is not clear at first sight whether we can calculate that. The trick is to use the law of total probability, as described below.

We should pause for a moment to think about what the underlying probability space is here to make sensible use of the law of total probability.

In the table above we have assigned probabilities to the potentially possible numbers of red socks in the bag. But by drawing a sock from the bag we have expanded the possible outcomes:

These now have to be considered as combinations:: They consist of the number of red socks in the bag, plus the outcome of drawing a sock from the bag. We can think of these as being encoded by

- a number from 0 to 3 (the number of red socks in the bag) and
- a colour,  $R$  or  $B$ , denoting the outcome of the draw.

In other words, for the moment we should think of the sample space as

$$\{0R, 0B, 1R, 1B, 2R, 2B, 3R, 3B\}.$$

Note that our original outcome  $i$  now becomes a shortcut for the event

$$\{iR, iB\}.$$

If we draw further socks from the bag then each current outcome  $iC$  will become an event

$$\{iC\mathbf{R}, iC\mathbf{B}\}.$$

Returning to the probability that a red sock is drawn,  $P(\textcolor{red}{R})$ , we can now see that this is the probability of the event

$$\{0\textcolor{red}{R}, 1\textcolor{red}{R}, 2\textcolor{red}{R}, 3\textcolor{red}{R}\}.$$

Since we can split this event into the disjoint union of

$$\{0\textcolor{red}{R}\} \cup \{1\textcolor{red}{R}\} \cup \{2\textcolor{red}{R}\} \cup \{3\textcolor{red}{R}\},$$

the law of total probability tells us that

$$\begin{aligned} P(\textcolor{red}{R}) &= P(\textcolor{red}{R} | 0)P(0) + P(\textcolor{red}{R} | 1)P(1) + P(\textcolor{red}{R} | 2)P(2) + P(\textcolor{red}{R} | 3)P(3) \\ &= 0 \cdot 1/4 + 1/3 \cdot 1/4 + 2/3 \cdot 1/4 + 3/3 \cdot 1/4 \\ &= 1/2. \end{aligned}$$

This should be no surprise: At the moment all the events 0 to 3 are considered to be equally likely, which gives us a symmetry that makes drawing a red and drawing a black sock equally likely, based on what we know so far.

We use this information to update our description of the situation.

First update		0	1	2	3	
	$P$	0	1/6	2/6 = 1/3	3/6 = 1/2	

Note that the probability that there is just one red sock has gone down, and that the socks are all read has gone up the most.

Assume another sock is drawn, and it is another red sock. This extends the sample space in that events are now of the form

$$i\textcolor{red}{RR}, i\textcolor{red}{RB}, i\textcolor{red}{BR}, i\textcolor{red}{BB}.$$

But the way most implementations of the algorithm work is not to look at it from that point of view. Instead of keeping track of the colour of the socks drawn so far the assumption is that everything we know about what happened so far is encoded in the probabilities that describe what we know about the current situation.

This has the advantage that what we have to do now looks very similar to what we did on the previous round of updates, and it means that one can write code that performs Bayesian updating which works for every round.

So again we are seeking to update  $P(i)$  by setting it to

$$P(i | \textcolor{red}{R}) = \frac{P(\textcolor{red}{R} | i) \cdot P(i)}{P(\textcolor{red}{R})},$$

where now the  $P(i)$  are those calculated in the previous iteration, the first update to the distribution. Note that the value of  $P(\textcolor{red}{R})$  has changed.

It is now

$$\begin{aligned}
 P(\textcolor{red}{R}) &= P(\textcolor{red}{R} | 0)P(0) + P(\textcolor{red}{R} | 1)P(1) + P(\textcolor{red}{R} | 2)P(2) + P(\textcolor{red}{R} | 3)P3 \\
 &= 0 \cdot 0 + 1/3 \cdot 1/6 + 2/3 \cdot 1/3 + 3/3 \cdot 1/2 \\
 &= 7/9.
 \end{aligned}$$

The updated probabilities are

Second update	$\begin{array}{c c c c c} & 0 & 1 & 2 & 3 \\ \hline P & 0 & 1/14 & 4/14 & 9/14. \end{array}$
---------------	--

If instead the second drawn sock had been black then we would have to update  $P(i)$  to

$$P(i | B) = \frac{P(B | i) \cdot P(i)}{P(B)},$$

where we can read off the probabilities of drawing a black sock given that there are a given number of red socks from the table

$i$	0	1	2	3
	$P(B   i)$	1	$2/3$	$1/3$

which means that

$$P(B | i) = (3 - i)/3,$$

and based on the probabilities after the first update we have

$$\begin{aligned}
 P(B) &= P(B | 0)P(0) + P(B | 1)P(1) + P(B | 2)P(2) + P(B | 3)P3 \\
 &= 3/3 \cdot 0 + 2/3 \cdot 1/6 + 1/3 \cdot 1/3 + 0 \cdot 1/2 \\
 &= 2/9.
 \end{aligned}$$

leading to updated probabilities of

Alternative second update	$\begin{array}{c c c c c} & 0 & 1 & 2 & 3 \\ \hline P & 0 & 1/2 & 1/2 & 0. \end{array}$
---------------------------	---

Note that in this case, the probabilities for both cases that have been ruled out, 0 and 3, have been set to 0. Based on what we have seen in this situation, that is a red sock being drawn followed by a black one, it seems reasonable to have the probabilities for the remaining options to be equal

We can see that Bayesian updating is a way of adjusting our model of the current situation by updating the probabilities we use to judge how likely we are to be in any of the given scenarios.

The preceding example is comparatively simple, but there are two issues worth looking at in the context of this example. The first of these is already hinted at in the example: What is the underlying probability space in a case like this?

The sample space changes with the number of socks drawn—one might

think of it as evolving over time. At the stage when  $n$  socks have been drawn from the bag the outcomes are best described in the form of strings

$$iX_1X_2 \cdots X_n,$$

where  $i \in \{0, 1, 2, 3\}$  and  $X_i \in \{\text{R}, \text{B}\}$  for  $1 \leq i \leq n$ . In other words, each outcome consists of the number of red socks, and the result of the sock draws conducted.

As we move from one sample space to the next each outcome

$$iX_1X_2 \cdots X_n$$

splits into two new outcomes,

$$iX_1X_2 \cdots X_n \text{R} \quad \text{and} \quad iX_1X_2 \cdots X_n \text{B}.$$

Note that what is happening here is that the number of red socks in the bag is *fixed* for the entirety of the experiment, and so the actual probability distribution for the first probability space (before the first sock is drawn) is one which

- assigns 1 to the actual number of socks and
- 0 to all the other potential numbers of red socks under consideration.

If, for example, the number of red socks in the bag is 1 then the actual probability distribution is

	0	1	2	3
$P$	0	1	0	0.

Under those circumstances, the actual probabilities for the probability space based on the set of outcomes

$$\{0\text{R}, 0\text{B}, 1\text{R}, 1\text{B}, 2\text{R}, 2\text{B}, 3\text{R}, 3\text{B}\}.$$

is

	0R	0B	1R	1B	2R	2B	3R	3B
$P$	0	0	1/3	2/3	0	0	0	0.

What Bayesian updating is trying to do is to *approximate* this actual probability distribution for the original set of outcomes in a number of steps.

Note that since we do not know what the actual distribution does, it is at first sight surprising that with what little information we have, we can write a procedure that will succeed in approximating the correct distribution. The probabilities used for  $P_i$  are quite different from the actual ones given above. But if we keep conducting our random experiments then our approximated distribution will almost certainly converge towards the actual distribution—see Fact 11 for a more precisely worded statement.

The underlying probability space is one where the set of events is the powerset of the sample space, but many events have the probability 0. We don't know what the distribution is, and so we cannot describe that space and use that description in our procedure.

Note that we are very careful about which events play a role in our calculation. These are of two kinds:

- The first kind consists of events whose probability we are trying to estimate. These are the outcomes from the original sample space which expand into events whose number of elements doubles each time we draw a sock.
- The second kind consists of events whose approximated probability is calculated by forming a ‘weighted average’ over all the events of the first kind. In other words, we are using all the data from our current approximation to give an approximated probability for those events. In the example, this is the probability of drawing a red/black sock. The aim here is to ensure that we do not introduce any additional uncertainty or bias into our calculations.

The reason Bayesian updating is so useful is that it allows us to approximate the unknown probability distribution by conducting experiments (or observing events), with very little information being required for the purpose. At each stage we treat the present approximating distribution as if it were the actual distribution, and we are relying on the idea that over time, the available information will tell us enough to ensure that our approximation gets better.

Note that it will not necessarily get better on every step—whenever a comparatively unlikely event (according to the actual distribution) occurs, our approximation is going to get worse on the next step! But there is the *Law of Large Numbers* Fact 11 which can be thought of as saying that if we keep repeating the same experiment (drawing a sock from the bag) often enough, then almost certainly we will see red socks appearing in the correct proportion.

It is worth pointing out that the idea in Bayesian updating relies on us being able to perform the same experiment more than once—if we don’t put the drawn sock back into the bag the idea does not work.<sup>18</sup>

An interesting question is also what we can do if the number of socks in the bag is unknown. It is possible instead to consider the possible ratios between red and black socks. The most general case would require us to cope with infinite sums (since there are infinitely many possible ratios), and that is beyond the scope of this unit. Note also that there is no way of starting with a probability distribution on all possible ratios that assigns to each ratio the same probability in the way we did here, see Proposition 4.4.

If the number of possible ratios is restricted, however, then one may employ the same idea as in the example above, see Exercise 76.

A fun example for Bayesian updating, created by my colleague Gavin Brown, can be found here: <http://www.cs.man.ac.uk/~gbrown/BTTF/>.

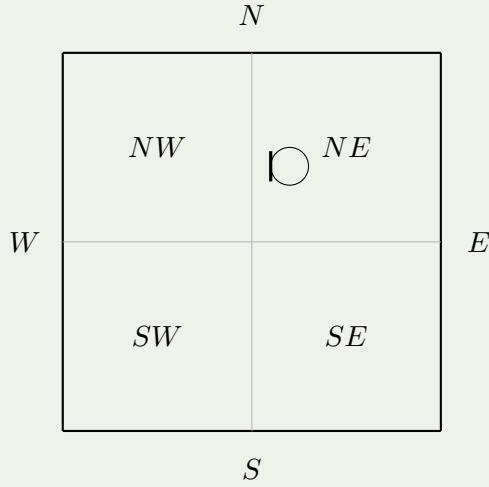

We present a toy<sup>19</sup> version of the following example to help you understand the more complex considerations in that example.

**Example 4.42.** Assume you have a robot that is in a room of size  $L \times l$  metres that has been split into four quadrants. The robot has a sensor, indicated by the line, which is known to face west.

---

<sup>18</sup>Of course, if the drawn sock is not returned then after three draws how many red socks were in the bag originally.

<sup>19</sup>What do you call a toy version of a toy version of an example?

The robot would like to determine which quadrant it is in. To do so it can invoke its sensor, which will detect how far it is to the nearest wall. Depending on whether the measured distance is smaller than  $l/2$  or larger than  $l/2$  the robot can then deduce whether it is in the quarter adjacent to that wall or not. However, the sensor is inaccurate, and will report a wrong distance  $1/4$  of the time.

Assume the robot has some information encapsulated in the following distribution:

Original distribution	$NW$	$NE$	$SE$	$SW$
$P$	0	2/6	1/6	3/6.

Assume the robot conducts a sensor reading and finds that the distance to the wall is less than  $l/2$ . We use  $C$  for ‘close’ to record this outcome (one might use  $F$  for ‘far’ if the measured distance is greater than  $l/2$ ). We can determine the probability that it gets this reading for each of the four possibilities:

$Q$	$NW$	$NE$	$SE$	$SW$
$P(C   Q)$	3/4	1/4	1/4	3/4.

It is close to the wall if it is in one of the two western quadrants, and it gets the correct reading with probability  $3/4$ . If it is in one of the eastern quadrants then it shouldn’t get this reading unless the measurement is inaccurate, which happens with probability  $1/4$ .

Using the law of total probability we may now calculate the probability that the robot gets this reading as

$$\begin{aligned}
 P(C) &= P(C | NW) \cdot P(NW) + P(C | NE) \cdot P(NE) \\
 &\quad + P(C | SE) \cdot P(SE) + P(C | SW) \cdot P(SW) \\
 &= \frac{1}{4} \cdot \frac{1}{6}(3 \cdot 0 + 1 \cdot 2 + 1 \cdot 1 + 3 \cdot 3) \\
 &= \frac{1}{4} \cdot \frac{1}{6} \cdot 12 \\
 &= \frac{1}{2}.
 \end{aligned}$$

We may now use Bayes' Theorem to find the formula for the updated probabilities of our distribution. Assume  $Q$  is one of the four quadrants. Then we want to update  $PQ$  to

$$\frac{P(C | Q) \cdot PQ}{PC},$$

leading to the following.

Updated distribution	NW	NE	SE	SW
$P$	0	1/12	2/12	9/12.

We can see that the probability that the robot is in the  $SW$  quadrant has gone up substantially—and indeed, given the fact that this was already the most likely position, the sensor reading further confirmed that opinion.

The following example is a more complicated version of the previous one but considerably simpler than its fully grown version which appears in COMP14112. It is included here to help you with the one you have to implement.

**Example 4.43.** We extend the previous example as follows: It is not known which way the robot is facing.

The location and orientation of the robot can then be described by a string of length 3, made up from the symbols  $\{N, E, S, W\}$ : The first two of the symbols give the quadrant in which the robot is, and the third its orientation. In the picture in Example 4.42 you can see a robot in state  $NEW$ .

The first symbol has to be  $N$  or  $S$ , and the second symbol has to be  $E$  or  $W$ , so altogether there are

$$2 \cdot 2 \cdot 4 = 16$$

possible states the robot could be in:

NEN	NEE	NES	NEW
NWN	NWE	NWS	NWW
SEN	SEE	SES	SEW
SWN	SWE	SWS	SWW

Again we assume that there is a probability distribution regarding which state the robot is in, either by assigning the same probability to each possible outcome, or by using partial information the robot has.

The robot is using a probability space where the outcomes are as in the table above. Since this is a finite set we can calculate the probability for each potential event, that is each subset of the sample space, by having a probability for each of the sixteen cases.

The robot can perform the same sensor readings as before. This means there is an event of taking a sensor reading, and the outcome can be that the nearest wall in the direction the robot is facing can be less than  $l/2$  or more than  $l/2$ . Hence we should think of the sample space as being given by strings of length four, where the last symbol tells us

whether the wall is close ( $C$ ) or far ( $F$ ). The robot, however, is only interested in the events consisting of the outcome where the last symbol has been ignored.

So where in the table above we wrote, for example,  $NEN$ , the underlying event is really  $\{NENC, NENF\}$ . We call these events ‘status events’ because they tell us the potential status of the robot.

Querying the sensor is another event, which we can think of as getting the reading  $C$ , or getting the reading  $F$ , where the former is given by the set

$$\begin{aligned} &\{NENC, NEEC, NESI, NEWC, \\ &NWNC, NWEC, NWSC, NWWC, \\ &SENC, SEEC, SESI, SEWC, \\ &SWNC, SWEC, SWSC, SWWC\}. \end{aligned}$$

It is convenient to abbreviate that event with  $C$ .

Based on what we’ve said above it should be clear that we know something about the conditional probabilities for sensor readings.

If the position of the robot is  $NEN$  then the nearest wall is close. The probability that the sensor reading will be  $C$  is therefore  $3/4$  (because the sensor is correct 75% of the time), and  $1/4$  that the reading will be  $F$ .

This means that we know that  $P(C | NEN) = 3/4$ , and similarly we can determine the conditional probabilities for  $C$  and  $F$  given the various other status events.

How should the robot update information about its status? It should apply Bayesian updating.

When the robot performs a sensor reading it should update the probability for all status events to reflect the result. If the sensor reading returns  $F$  then the probability that the robot is in, for example, square  $NEN$  should reduce, since if everything works properly the sensor should return  $C$  in that situation. The new value for the probability of  $NEN$  should be

the probability of  $NEN$  given the outcome  $F$ .

In other words, we would like to set  $P(NEN)$  to

$$P(NEN | F).$$

To calculate that probability we can use Bayes’s Theorem which tells us that

$$P(NEN | F) = \frac{P(F | NEN) \cdot P(NEN)}{PF}.$$

We know that  $P(F | NEN)$  is  $1/4$ , and we know the current probability for  $NEN$ . Hence it only remains to calculate  $PF$ . For this remember that  $F$  is a shortcut for all events of the form ??? $F$ , that is, the last symbol is  $F$ . We have a pairwise disjoint collection of events with the

property that  $F$  is a subset of their union, since

$$\begin{aligned} F &= \{NENF\} \cup \{NEEF\} \cup \{NESF\} \cup \{NEWF\} \\ &\quad \cup \{NWNF\} \cup \{NWEF\} \cup \{NWSF\} \cup \{NWWF\} \\ &\quad \cup \{SENF\} \cup \{SEEF\} \cup \{SESF\} \cup \{SEWF\} \\ &\quad \cup \{SWNF\} \cup \{SWEF\} \cup \{SWSF\} \cup \{SWWF\} \\ &= \bigcup_{X \in \{N,S\}, Y \in \{E,W\}, Z \in \{N,E,S,W\}} \{XYZF\}. \end{aligned}$$

Hence we may use the law of total probability to deduce that

$$PF = \sum_{X \in \{N,S\}, Y \in \{E,W\}, Z \in \{N,E,S,W\}} P(F | XYZF) \cdot P(XYZF).$$

This means we now can calculate the updated probability for  $NEN$ .

In general, given a status event  $L$  (for location), the robot should update the probability for  $L$  to account for the outcome of querying the sensor, so if the outcome is  $C$ , it should set

$$P(L) \quad \text{to} \quad P(L | C).$$

More generally, if we use  $D$  (for distance) for an element of the set  $\{C, F\}$  then the robot should set

$$P(L) \quad \text{to} \quad P(L | D),$$

after it has observed the event  $D$ . How do we calculate this? We are given

- the probabilities  $P(L)$ ,
- the probabilities  $P(D | L)$  for  $D \in \{C, F\}$ .

As discussed above Bayes's Theorem allows us to calculate the desired probability. It tells us that for each status event  $L$  we have

$$P(L | D) = \frac{P(D | L) \cdot PL}{PD}.$$

Looking at the probabilities that appear on the right hand side of this equality, we know  $P(D | L)$  from the basic setup (information about the robot's sensor), and we have a value for  $PL$  since that is what the robot is keeping track of. What about  $PD$ ?

Remember that this is a shortcut for all events of the form  $???D$ , so repeating what we have done above for the case where  $D$  is equal to  $F$  we can see that we have a pairwise disjoint collection of events with the

property that  $D$  is a subset of their union, since

$$\begin{aligned}
D &= \{NEND\} \cup \{NEED\} \cup \{NESD\} \cup \{NEWD\} \\
&\quad \cup \{NWND\} \cup \{NWED\} \cup \{NWS\} \cup \{NWW\} \\
&\quad \cup \{SEND\} \cup \{SEED\} \cup \{SESD\} \cup \{SEWD\} \\
&\quad \cup \{SWND\} \cup \{SWED\} \cup \{SWS\} \cup \{SWWD\} \\
&= \bigcup_{X \in \{N,S\}, Y \in \{E,W\}, Z \in \{N,E,S,W\}} \{XYZD\}.
\end{aligned}$$

Hence we may use the law of total probability to deduce that

$$PD = \sum_{X \in \{N,S\}, Y \in \{E,W\}, Z \in \{N,E,S,W\}} P(D | XYZD) \cdot P(XYZD).$$

The expressions we have found here get quite unwieldy. In the version of this scenario that you see in COMP14112, the notation changes to make this easier. We show how to adapt that notation to our toy example, and give these equalities using that notation.

Instead of writing  $XYZ$  to describe the potential location and orientation of the robot, let's call the events in question

$$L_{i,j,k},$$

where

- $i \in \{0, 1\}$ , where 0 stands for  $N$  and 1 for  $S$ ,
- $j \in \{0, 1\}$ , where 0 stands for  $E$  and 1 for  $W$ , and
- $k \in \{0, 1, 2, 3\}$ , where 0 stands for  $N$ , 1 for  $E$ , 2 for  $S$  and 3 for  $W$ .

Our encoding means that  $L_{0,0,3}$  is equivalent to the status event  $NES$ . We can then write the update rule for the probabilities as follows: After a sensor reading resulting in  $D$  (where  $D$  is still in  $\{C, F\}$ ), the probability

$$PL_{i,j,k}$$

should be set to

$$\begin{aligned}
P(L_{i,j,k} | D) &= \frac{P(D | L_{i,j,k}) \cdot PL_{i,j,k}}{\sum_{i' \in \{0,1\}, j' \in \{0,1\}, k' \in \{0,1,2,3\}} P(D | L_{i',j',k'}) \cdot PL_{i',j',k'}} \\
&= \frac{P(D | L_{i,j,k}) \cdot PL_{i,j,k}}{\sum_{i',j',k'} P(D | L_{i',j',k'}) \cdot PL_{i',j',k'}},
\end{aligned}$$

where the last line is a short-cut for the case when it is understood what values the variables  $i'$ ,  $j'$  and  $k'$  are allowed to take.

You may want to return to these notes when you reach this material on COMP14112 to help with working out how to update the probabilities for the more complicated scenario you will study there.

In general, Bayesian updating is performed in the situation where we have the following.

- There are a number of possibilities that may apply, say  $Q_1, Q_2, \dots, Q_n$

which are events in some probability space such that they are disjoint, and their union is the whole sample space. It is assumed that there are estimates  $P(Q_i)$  for all  $1 \leq i \leq n$ .

- There is a way of collecting information about the situation, in such a way that there are a number of outcomes  $s_1, s_2, \dots, s_m$ , and so that each event  $Q_i$  can be thought of as

$$Q_i = \{Q_i s_1, Q_i s_2, \dots, Q_i s_m\}.$$

- When the outcome  $s_k$  is observed then for each  $Q_i$  its probability is updated to

$$P(Q_i | s_k) = \frac{P(s_k | Q_i) \cdot P(Q_i)}{P(s_k)},$$

where it is assumed that  $P(s_k | Q_i)$  is known for all combinations, and where the calculation of  $P(s_k)$  is performed as

$$P(s_k) = \sum_{i=1}^n P(s_k | Q_i) \cdot P(Q_i),$$

giving an overall update of  $P(Q_i)$  to

$$\frac{P(s_k | Q_i) \cdot P(Q_i)}{\sum_{i=1}^n P(s_k | Q_i) \cdot P(Q_i)}.$$

### Tip

To perform Bayesian updating you need to perform the following steps:

- Determine the possibilities you want to distinguish between. Initialize the probability distribution  $P$  by setting all probabilities to be equal, unless you have further information.
- Determine which random experiment you may conduct to find out more about the given situation. For each outcome  $s$  of this experiment, and for each possibility  $Q$  from the first step, determine

$$P(s | Q).$$

You must be able to find these numbers from the description of the situation. These numbers are used on every step of the calculation and they do not change.

- Assume you carry out the experiment once, and find the outcome  $s$ . Calculate

$$Ps = P(s | Q_1) \cdot PQ_1 + P(s | Q_2) \cdot PQ_2 + \dots + P(s | Q_n) \cdot PQ_n,$$

where  $Q_1, Q_2, \dots, Q_n$  are all the possibilities determined in step 1, the  $P(Q_i)$  come from the current estimate of the probability distribution, and the  $P(s|Q_i)$  were determined in step 2. This number has to be recalculated after each update to the distribution.

- Update the probability distribution  $P$  by setting

$$P(Q_i) = \frac{P(s | Q_i) \cdot P(Q_i)}{P_s}.$$

where these numbers were determined in the previous steps, and repeat from step 3.

**Example 4.44.** In Example 4.42 we have the following:

- The possibilities  $Q_i$  we are trying to distinguish between are the four quadrants.
- The outcomes of the experiment that can be conducted to collect further information are  $C$  and  $F$ .
- One may determine the probability of recording  $C$  given that the current position is  $Q$  (and similarly for  $F$ ). The table for  $C$  is given in the example. We give the table for  $F$  here:

$Q$	$NW$	$NE$	$SE$	$SW$
$P(F   Q)$	1/4	3/4	3/4	1/4

Note that if the robot turns to face in a different direction then these numbers change.

- One may now compute  $PC$  (or  $PF$ ) using the law of total probability.
- It is now possible to update the distribution using Bayes's Theorem, and then one repeats from step 3.

**Example 4.45.** In Example 4.41 we have the following.

- The possibilities  $Q_i$  we are trying to distinguish between are the possible number of red socks, that is 0, 1, 2 or 3, At the start the distribution  $P$  assigns to each outcome the probability 1/4.
- The outcomes of the experiment we can conduct repeatedly are the two possible colour of the sock drawn,  $R$  and  $B$ .
- The probability of drawing a red sock if the total number of red socks is  $i$  as  $i/3$  (and the probability of drawing a black sock as  $1 - i/3$ ).
- One may now calculate  $P(R)$  using the law of total probability.
- One may now update the distribution  $P$  using Bayes's Theorem, and then repeat from step 3.

**Example 4.46.** In Example 4.43 we had the following.

- The possibilities  $Q_i$  we are trying to distinguish between are the

various quadrants and the direction in which the robot's sensor is facing. We assume there is a given probability distribution  $P$  at the start.

- The outcomes of the experiment we could conduct repeatedly are the two possible outcomes of using the sensor,  $C$  and  $F$ .
- We determine the probability of getting  $C$  (or  $F$ ) for each possibility  $Q_i$  based on the probability of the sensor working accurately, and the currently assumed situation  $Q_i$  using the law of total probability.
- Using Bayes's Theorem one may use this data to update the probability distribution.

**CExercise 74.** Imagine your friend claims to have an unfair coin, which they give to you. From the rather vague description they gave you you aren't sure whether the coin is fair, or whether it gives heads with probability  $3/4$ , or whether it gives tails with that probability. You want to conduct Bayesian updating to work out which it is.

You are going to mimic having the coin as follows: Take two coins. Every time you would toss the our fictitious coin, toss both your coins. If at least one of them shows  $H$ , assume the result was  $H$ , else assume it was  $T$ .

Use Bayesian updating to carry out three updates.

**Exercise 75.** Assume a friend is trying to send you a message which consists of 'yes' or 'no'. He's a bit mischievous, and what he is actually going to do is tell three of your friends something which he claims you can decode into a 'yes' or a 'no' each time.

You are very sceptical about whether you will be able to extract the correct message from your friends, and you only give yourself a 60% chance to do so correctly in each case.

Carry out Bayesian updating to determine your friend's answer. Assume that the messages you extract from your three friends are 'yes', 'yes' and 'no' in that order.

What do you think of the final distribution? How confident are you that you have decoded the message correctly?

**Exercise 76.** Consider Example 4.41. Instead of knowing the total number of socks, all you know is that the ratio of red to black socks is an element of the following set:

$$\{1/4, 1/3, 1/2, 2/3\}.$$

What is the Bayesian update rule for this situation? Assume a black sock is drawn, followed by a red one. Starting from a probability distribution

that assigns the value of  $1/4$  to each ratio, give the updated probabilities for each of the given ratios after each draw.

**Optional Exercise 16.** Assume you are asked to perform Bayesian updating in a case where there are only two possible options, and where information is gained by performing an experiment which also has two possible outcomes.

The resulting case can be described using three parameters:

- The probability  $p$  that we have assigned to the first case'
- the probability  $q$  that tells us how likely Outcome 1 is if we are in Case 1 and
- the probability  $r$  that tells us how likely Outcome 1 is if we are in Case 2.

Write down the rule for a Bayesian update in this situation. Can you say anything about subsequent calculations?

## 4.4 Random variables

Often when we study situations involving probabilities we want to carry out further calculations. For example, in complexity theory (see COMP11212 and COMP26120) we are frequently looking for the ‘average case’—that is, we would like to know what happens ‘on average’. By this one typically means taking all the possible cases, each weighted by its relative frequency (not all cases may be equally frequent), and forming the average over all those. For examples of what is meant by an ‘average case’ for two search algorithms see Examples 4.90 to 4.93.

But in order to carry out these operations we have to be in a situation where we can *calculate* with the values that occur. If we look at some of the examples studied then we can see that some of them naturally lend themselves to calculating averages (it is possible, for example, to ask for the average number of eyes shown when throwing two dice), and some don’t (there’s no average colour of a sock drawn from one of our bags of socks).

This is why people often design questionnaires by giving their respondents a scale to choose from. The university does this as well: When you will be asked to fill in course unit questionnaires for all your units, then part of what you are asked to do is to assign numbers. ‘On a scale of 1 to 5, how interesting did you find this unit.’ This allows the university to form averages. But what does it mean that the average interest level of COMP11120 was 3.65 (value from 2014/15)?<sup>20</sup> Certainly every time you assign numbers so that you may form averages, you should think about what those numbers are supposed to mean, and whether people who are asked to give you numbers are likely to understand the same as you, and as each other, by those numbers.

---

<sup>20</sup>On these questionnaires they try to make the numbers slightly more meaningful by assigning 5 to ‘agree’ and 1 to ‘disagree’, but when does one move from one grade to another? Is it really meaningful to average those out?

Nonetheless, forming averages can be a very useful action to perform, and that is why there is a name given to functions that turn the outcomes from some probability spaces into numbers. We see below that this does not merely allow us to calculate averages but also to describe particular events without knowing anything about the events or outcomes from the underlying probability space.

#### 4.4.1 Random variables defined

Random variables are functions that translate the elements of a sample space, that is the possible outcomes from a random experiment, to real numbers. But this translation has to happen in such a way that we know what the probabilities for the resulting numbers are, and that requires a technical definition. In order to formulate that we have to define an additional concept.

##### Definition 31: measurable function

Let  $(S, \mathcal{E}, P)$  be a probability space. The function

$$f: S \rightarrow \mathbb{R}$$

is *measurable* if and only if for all elements  $r$  of  $\mathbb{R}$  the sets

- $\{s \in S \mid fs \leq r\}$  and
- $\{s \in S \mid r \leq fs\}$

are events, that is, elements of  $\mathcal{E}$ .

Note that in the case where  $\mathcal{E} = \mathcal{P}S$ , as is often the case for applications, every function from  $S$  to  $\mathbb{R}$  is measurable.

##### Definition 32: random variable

Given a probability space  $(S, \mathcal{E}, P)$  a **random variable** over that space is a measurable function from  $S$  to  $\mathbb{R}$ .

**Example 4.47.** When we toss a coin, but record the outcomes as numbers, say 0 for heads and 1 for tails, you have a random variable.

**Example 4.48.** If you have a population whose height distribution you know (compare Example 4.59) you may think of randomly picking a person and recording their height as a random variable.

**Example 4.49.** When you're playing a game of chance, and you assign a value of  $-1$  to losing,  $0$  to a draw and  $1$  to a win, you have a random variable. You could also give  $3$  for a win,  $1$  for a draw, and  $0$  for a loss, and that would also result in a random variable.

Note that whenever we assign numbers to outcomes, and then carry out calculations with those numbers, we have to worry about whether our interpretation of those numbers makes sense. In game theory it is customary to use any items (money or points) won or lost to encode the outcome of a game in a number, but that may not be a faithful description of what a win or loss means to the individual playing.

Whenever you have a probability space  $(S, \mathcal{E}, P)$  such that the set of outcomes  $S$  is a subset of  $\mathbb{R}$  then you have a probability variable, provided you can calculate the probabilities of all sets of the form

$$S \cap [r, \infty] \quad \text{and} \quad S \cap (-\infty, r],$$

where  $r \in \mathbb{R}$ .

For some random experiment one would naturally record the outcome as a number, and that gives a random variable, but in other cases one has to translate the outcome to a real number first. See the first example given above, but also more interestingly see the following example.

**Example 4.50.** If you are plotting the position of a butterfly in the form of two coordinates,  $(x, y)$ , then to get a random variable you have to turn those two numbers into one. You could, for example, compute the distance of the butterfly from a fixed point, and that could be considered a random variable.

Technically this amounts to doing the following. We have a probability space with underlying sample set  $\mathbb{R} \times \mathbb{R}$ , and a set of events based on the Borel  $\sigma$ -algebra, where all sets of the form

$$[r, r'] \times [s, s'],$$

for  $r, r', s, s' \in \mathbb{R}$  are events. We assume that there is a probability density function describing the probability that the butterfly is at point a given point  $(x, y)$ . One suitable such function is

$$\begin{aligned} \mathbb{R} \times \mathbb{R} &\longrightarrow \mathbb{R}^+ \\ (x, y) &\longmapsto \frac{e^{-1/2(x^2+y^2)}}{2\pi}. \end{aligned}$$

To create a random variable we would like to apply the function

$$\begin{aligned} \mathbb{R} \times \mathbb{R} &\longrightarrow \mathbb{R} \\ (x, y) &\longmapsto \sqrt{x^2 + y^2} \end{aligned}$$

to the location, which gives us the butterfly's distance from some chosen point that here is assumed to be  $(0, 0)$ . We have taken two-dimensional data and turned it into a random variable, which requires the restriction to just one dimension.

**Example 4.51.** Consider Example 4.22 where we have given several probability spaces one might use to describe throwing two dice. If you

pick as the space the one with outcomes

$$\{(i, j) \mid i, j \in \{1, 2, 3, 4, 5, 6\}\},$$

then the function which maps the pair  $(i, j)$  from that set to the sum of eyes shown

$$i + j,$$

(viewed as an element of  $\mathbb{R}$ ) is a random variable<sup>21</sup>

$$\begin{aligned} X: \{1, 2, 3, 4, 5, 6\} \times \{1, 2, 3, 4, 5, 6\} &\longrightarrow \mathbb{R} \\ (i, j) &\longmapsto i + j. \end{aligned}$$

Whenever we have a random variable we get an induced probability distribution. In order to calculate the probability that  $X$  takes the value 4 we have to calculate<sup>22</sup>

$$\begin{aligned} P(\{(i, j) \in \{1, 2, 3, 4, 5, 6\} \times \{1, 2, 3, 4, 5, 6\} \mid X(i, j) = 4\}) \\ = P(\{(1, 3), (2, 2), (3, 1)\}) \\ = P(\{(1, 3)\}) + P(\{(2, 2)\}) + P(\{(3, 1)\}) \\ = \frac{1}{36} + \frac{1}{36} + \frac{1}{36} \\ = \frac{3}{36} = \frac{1}{12}. \end{aligned}$$

This is usually written in the shortcut notation of

$$P(X = 4).$$

But note that since we have translated our outcomes into real numbers we may also ask, for example, what the following probabilities are:

$$\begin{aligned} P(X \leq 4) \\ P(X \leq -4) \\ P(X \leq 5.5) \\ P(X \geq 10) \end{aligned}$$

The events described here do not look as if they have anything to do with the original experiment of rolling two dice, but since we have translated the outcome from that experiment into real numbers we may construct such events.

These probabilities can be calculated as follows:

- $P(X \leq 4)$ . This can be calculated by splitting it into the possible outcomes satisfying that property.

$$\begin{aligned} P(X \leq 4) &= P((X = 2) \cup (X = 3) \cup (X = 4)) \\ &= P(X = 2) + P(X = 3) + P(X = 4) \\ &= \frac{1}{36} + \frac{2}{36} + \frac{3}{36} = \frac{1}{6}. \end{aligned}$$

- $P(X \leq -4)$ . Clearly there are no possible outcomes which satisfy this condition, so this probability is 0.
- $P(X \leq 5.5)$ . This works similar to the first calculation.

$$\begin{aligned}
P(X \leq 5.5) &= P((X = 2) \cup (X = 3) \cup (X = 4) \cup (X = 5)) \\
&= P(X = 2) + P(X = 3) + P(X = 4) + P(X = 5) \\
&= \frac{1}{36} + \frac{2}{36} + \frac{3}{36} + \frac{4}{36} = \frac{10}{36} = \frac{5}{18}.
\end{aligned}$$

- $P(X \geq 10)$ . This is similar to the previous example.

$$\begin{aligned}
P(X \geq 10) &= P(X = 10) + P(X = 11) + P(X = 12) \\
&= \frac{3+2+1}{36} = \frac{1}{6}.
\end{aligned}$$

Below we describe how this works for arbitrary random variables.

In general given a random variable  $X$  on a sample space  $(S, \mathcal{E}, P)$ , and real numbers  $r$  and  $r'$ , we define

- $P(r \leq X \leq r') = P\{s \in S \mid r \leq X(s) \leq r'\}$
- $P(r \leq X) = P\{s \in S \mid r \leq X(s)\}$ ,  
 $P(r < X) = P\{s \in S \mid r < X(s)\}$ ,
- $P(X \leq r') = P\{s \in S \mid X(s) \leq r'\}$ ,  
 $P(X < r) = P\{s \in S \mid X(s) < r\}$ .

The general case is given by the following proposition.

#### Proposition 4.7

Let  $X$  be a random variable over the probability space  $(S, \mathcal{E}, P)$ . The probability distribution of  $X$  is determined by the fact that, for any real interval  $I$  we have

$$P(X \in I) = P\{s \in S \mid X(s) \in I\}.$$

In other words, if we are given an interval in  $\mathbb{R}$  then in order to determine its probability we ask for the probability of the event given by all those elements of the original sample space which are mapped into that interval. Note that the sets that appear on the right hand side of the equal sign appear in the definition of measurability. This ensures that in the original probability space we have a probability for the set in question.

#### Definition 33: discrete/continuous random variable

A random variable  $X$  is **discrete** if and only if its range is a countable<sup>21</sup> subset of  $\mathbb{R}$ . A random variable which is not discrete is **continuous**.

---

<sup>21</sup>Random variables are typically named using capital letters from the end of the alphabet.

<sup>22</sup>You may want to return to Example 4.22 for an explanation.

While there is a mathematical theory that allows the discrete case to be treated at the same time as the continuous one, covering the mathematics that allows this is beyond the scope of this course unit. In what follows the discrete case is frequently treated separately. In the text, and in some of the results given, some guidance is given on how the discrete case may be seen as a special case of the continuous one.

Note in particular that if a random variable  $X$  has a finite range, then Proposition 4.7 indicates that we can treat it in much the same way as we did a probability space with a finite sample set where every set of the form  $\{s\}$ , for  $s \in S$ , is an event.

**Example 4.52.** If we look at Example 4.47 it is clear that there are only two possible outcomes of the given random variable  $X$ , namely 0 and 1, and that each of those occurs with probability 1/2.

This means that when we calculate the probability

$$P(X \leq r),$$

then this is completely determined by which of 0 and 1 is in the given interval. In particular we have

$$P(X \leq r) = \begin{cases} 0 & r > 0 \\ 1/2 & 0 \leq r < 1 \\ 1 & \text{else.} \end{cases}$$

Note that every discrete random variable has a range of the form

$$\{r_i \in \mathbb{R} \mid i \in \mathbb{N}\},$$

that is a subset of  $\mathbb{R}$  that is indexed by the natural numbers. For such a random variable, say  $X$ , further note that

$$X = r_i, \quad \text{for } i \in \mathbb{N}$$

gives us a collection of pairwise disjoint events which collectively have probability 1, as you are asked to show in the following exercise.

**Exercise 77.** Let  $X$  be a discrete random variable with range

$$\{r_i \in \mathbb{R} \mid i \in \mathbb{N}\}.$$

Show that

$$\sum_{i \in \mathbb{N}} P(X = r_i) = 1.$$

**Example 4.53.** Assume we are conducting a random experiment that consists of tossing a coin three times. In order to record the possible outcomes we can use strings of length three which give the outcomes for

---

<sup>23</sup>What this means formally is discussed in Section 5.2. Every finite set is countable, and you may think of countable sets as ones that can be described in the form  $\{s_i \mid i \in \mathbb{N}\}$ .

each toss, resulting in the sample space

$$S = \{HHH, HHT, HTH, HTT, THH, THT, TTH, TTT\}.$$

This means we can describe the elements of  $S$  via

$$S = \{s_1s_2s_3 \mid s_1, s_2, s_3 \in \{H, T\}\}.$$

Each of these occurs with probability  $1/8$ . We can turn this experiment into a random variable by converting each outcome into a number. Here we pick the number of heads shown.

The resulting random variable, say  $X$ , has the following range:

$$\{0, 1, 2, 3\}.$$

since the number of heads may range from 0 to 3. In order to find the probability of each of the possible results we have to work out which events are mapped to which number. Recall that a random variable is a *function*, and our function is given by

$$\begin{array}{ccc} \{S\} & \xrightarrow{\hspace{2cm}} & \mathbb{R} \\ s_1s_2s_3 & \longmapsto & \text{no of } H \text{ in } s_1s_2s_3. \end{array}$$

The probability for each possible value for  $X$  is given by adding all the probabilities of outcomes from the original space which are mapped to it. For example,

$$\begin{aligned} P(X = 2) &= P\{s_1s_2s_3 \in S \mid \text{no of } H \text{ is } 2\} \\ &= P\{HHT, HTH, THH\} \\ &= \frac{1}{8} + \frac{1}{8} + \frac{1}{8} \\ &= \frac{3}{8}. \end{aligned}$$

We can conveniently give these probabilities in a table. To help illustrate how those probabilities come about we also give the outcomes from the original space in the column of the number they are mapped to by  $X$ .

	$HTT$	$HHT$	
$TTT$	$THT$	$HTH$	$HHH$
	$TTH$	$THH$	
<hr/>	<hr/>	<hr/>	<hr/>
0	1	2	3
<hr/>	<hr/>	<hr/>	<hr/>
$1/8$	$3/8$	$3/8$	$1/8$

This is the *probability mass function* for the random variable, which is formally defined below. We can now ask questions such as what is the probability that the number of heads is at most 2, or what is the average number of heads tossed.

**Exercise 78.** Consider the experiment that consists of tossing a fair coin four times. Consider the random variable  $X$  which records the number

of heads thrown. Calculate the following probabilities.

- (a)  $P(X = 2),$
- (b)  $P(X \leq 3),$
- (c)  $P(X \leq \pi),$
- (d)  $P(X \geq 3),$
- (e)  $P(X \geq 10),$
- (f)  $P(X < -1).$
- (g)  $P((X = 1) \cup (X = 3)).$

(h)  $P(X \text{ is even}).$  Note that this only makes sense because we know the range of  $X$  is a subset of  $\mathbb{N}$ —it does not make sense to talk of evenness for numbers in  $\mathbb{R}$ .

#### 4.4.2 A technical discussion

What follows is a fairly technical discussion regarding why we can define probabilities in the way outlined above. The material from this subsection is not examinable, and you should feel free to skip it when reading the notes.

**Optional Exercise 17.** Show that if  $(S, \mathcal{E}, P)$  is a probability space, and  $f: S \rightarrow \mathbb{R}$  is a measurable function, then given  $r$  and  $r'$  in  $\mathbb{R}$  we have that

$$P(r \leq X \leq r')$$

is an event; in other words, the probability that appears above is always defined.

#### Proposition 4.8

Let  $(S, \mathcal{E}, P)$  be a probability space, and let  $f: S \rightarrow \mathbb{R}$  be a function. If  $f$  is measurable then for every  $B$  in the Borel  $\sigma$ -algebra  $\mathcal{E}_B$  on  $\mathbb{R}$  we have that

$$\{s \in S \mid fs \in B\}$$

is an event, that is an element of  $\mathcal{E}$ .

#### Proposition 4.9

Let  $(S, \mathcal{E}, P)$  be a probability space, and let be  $f: S \rightarrow \mathbb{R}$  a measurable function. For  $i \in \mathbb{N}$  let  $I_i$  be an interval in  $\mathbb{R}$  such that the the  $I_i$  are pairwise disjoint. If we define, for  $i \in \mathbb{N}$ ,

$$E_i = \{s \in S \mid fs \in I_i\},$$

then the  $E_i$  are pairwise disjoint and so

$$\begin{aligned} P\left(\bigcup_{i \in \mathbb{N}} I_i\right) &= P\left(\bigcup_{i \in \mathbb{N}} E_i\right) \\ &= \sum_{i \in \mathbb{N}} PE_i \\ &= \sum_{i \in \mathbb{N}} PI_i. \end{aligned}$$

As a consequence we get the following result:

### Theorem 4.10

Let  $(S, \mathcal{E}, P)$  be a probability space, and  $f: S \rightarrow \mathbb{R}$  a measurable function. Then a probability space is given by  $\mathbb{R}$ , the Borel  $\sigma$ -algebra  $\mathcal{E}_B$ , and the probability distribution

$$\begin{aligned} \mathcal{E}_B &\longrightarrow [0, 1] \\ E &\longmapsto P(\{s \in S \mid fs \in E\}). \end{aligned}$$

**Example 4.54.** Looking back at Example 4.52 we can see how we have effectively defined a probability distribution for  $\mathbb{R}$ . It can be described as follows: Given an element  $E$  of the Borel  $\sigma$ -algebra  $\mathcal{E}_B$  the probability of  $E$  is given as

$$PE = \begin{cases} 0 & 0, 1 \notin E \\ 1/2 & \text{exactly one of } 0, 1 \text{ in } E \\ 1 & \text{else.} \end{cases}$$

In general, if a random variable  $X$  has a finite range,<sup>24</sup> say

$$\{r_1, r_2, \dots, r_n\} \text{ in } \mathbb{R}$$

then given an interval  $I$  we have that

$$P(X \in I) = P(I \cap \{r_1, r_2, \dots, r_n\}) = \sum_{i \in \{1, 2, \dots, n\}, r_i \in I} P(X = r_i).$$

In other words we add up all the probabilities for those elements  $r_i$  of the range of  $X$  which are elements of  $I$ .

Alternatively we may restrict ourselves to the range of the underlying measurable function to define a probability space—in this way we remove those parts of  $\mathbb{R}$  which are assigned a probability of 0.

### Theorem 4.11

Let  $(S, \mathcal{E}, P)$  be a probability space, and  $f: S \rightarrow \mathbb{R}$  a measurable function. Then a probability space is given by the range  $T$  of  $f$ , the  $\sigma$ -algebra

$$\{E \cap T \mid E \in \mathcal{E}_B\},$$

---

<sup>24</sup>This result can be extended to the case where  $X$  has a range that can be expressed as  $\{r_i \mid i \in \mathbb{N}\}$ .

and the probability distribution

$$\begin{aligned} \{E \cap T \mid E \in \mathcal{E}_B\} &\longrightarrow [0, 1] \\ B &\longmapsto P(\{s \in S \mid fs \in B\}). \end{aligned}$$

**Example 4.55.** If we once again look at Example 4.52 then the range of the random variable is  $\{0, 1\}$ . The set of events given in the previous theorem is then merely the powerset of this set. The probability distribution is given by the following assignment:

$$\begin{aligned} P\emptyset &= 0 \\ P\{0\} = P\{1\} &= \frac{1}{2} \\ P\{0, 1\} &= 1. \end{aligned}$$

#### 4.4.3 Calculating probabilities for random variables

Above we define probabilities for random variables. You can think of them as translating the original outcomes into numbers in such a way that we can look at the probabilities of subsets of  $\mathbb{R}$  instead of events from the original space. The previous section establishes that we can take the original probability distribution and transfer it to the random variable, which gives another probability distribution, this time over the real numbers, which means that all the usual results (see Sections 4.2.5 and 4.3.3) hold.

One of the advantages of considering random variables is that it allows us to compute probabilities with very little information, in particular without knowing too much about the original probability space.

**Example 4.56.** Assume that  $X$  is a random variable and that we know that

- $P(X = 1) = 1/2$ ,
- $P(X = 2) = 1/4$ , and
- $P(X \geq 2) = 1/2$ .

This is enough to allow us to calculate, for example

- $P(X = 0) = 0$ ,
- $P(X \leq .5) = 0$ ,
- $P(X > 2) = 1/4$ .

We can see from the given information that the total probability of 1 is distributed in the following way:

- 1/2 of the available ‘probability mass’ goes to 1;
- 1/4 of it goes to 2;

- the remaining  $1/4$  goes to the interval  $(2, \infty)$ , and we cannot tell more precisely where it goes from the given data.

In particular this means that none of the probability goes to 0, or to any number below 1, which explains the first two claims. We can also derive the final result more formally by noting that

$$(X \geq 2) = (X = 2) \cup (X > 2)$$

and that the two sets whose union we form are disjoint, which means we have

$$1/2 = P(X \geq 2) = P(X = 2) + P(X > 2) = 1/4 + P(X > 2),$$

from which we may deduce the last result.

Note in particular that we do not know whether  $X$  is a discrete or a continuous random variable! The fact that it has non-zero probability for being equal to 1 and 2 might suggest it is the former, but it could still be the case that the behaviour is continuous for values beyond 2.

See Example 4.69 for a way of picturing some of this information.

**Example 4.57.** Recall Example 4.53, where we look at a random variable  $X$  given by the number of heads recorded when tossing a coin three times.

For this random variable we can see, for example, that

$$P(X > 2) = P(X = 3) = \frac{1}{8},$$

of that

$$P(X \leq .5) = P(X = 0) = \frac{1}{8},$$

and that

$$P(X \in (-\infty, -2] \cup [5, \infty)) = 0.$$

Because we know that we may consider the outcomes as real numbers we can write down (and calculate) the probability for the random variable taking its value in any interval, for example. This is quite useful, and in Section 4.4.4 we demonstrate that we can also use this to graphically represent the given probability distribution.

**Exercise 79.** Assume you have a probability space with outcomes

$$\{s_1, s_2, s_3, s_4, s_5\},$$

and that the following hold:

- The outcomes  $s_1$  and  $s_2$  are equally likely.
- The outcomes  $s_3$ ,  $s_4$  and  $s_5$  are equally likely.
- The outcomes of the first kind are three times as likely as the outcomes of the second kind.

A random variable is given by the function  $X$  defined by

$$X : \{s_1, s_2, s_3, s_4, s_5\} \xrightarrow{\quad} \mathbb{R}$$

$$x \longmapsto \begin{cases} 1 & x = s_1 \text{ or } x = s_2 \\ 3 & x = s_3 \\ 5 & \text{else.} \end{cases}$$

Compute the following:

- (a)  $P(X \leq 1.5)$ ,
- (b)  $P(X \geq 3)$ ,
- (c)  $P(2.5 \leq X \leq 3.2)$ ,
- (d)  $P(X \geq 6)$ .

Sometimes we want to take a random variable, which is a function that maps outcomes to real numbers), and apply another function to it so as to translate the outcomes.

**Example 4.58.** For a very simple-minded example, take the random variable  $X$  from Example 4.53. which counts the number of heads in a sequence of three coin tosses. Instead we might want to count the number of tails. Instead of defining a new random variable  $Y$  from scratch we may obtain it from  $X$  by composing with the function

$$\begin{aligned} \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto 3 - x \end{aligned} .$$

We may then compute the probability distribution for the range of  $Y$  from that of  $X$ .

	0	1	2	3
X	1/8	3/8	3/8	1/8
Y	1/8	3/8	3/8	1/8

Since the situation is completely symmetric the distributions happen to coincide, but that is not usually the case.

For a slightly more interesting example consider the following.

**Example 4.59.** Assume that I've been given the measures in height of a group of people, where the measures have been carried out with great precision. If I have the measures for everybody in the population I can give the probability distribution of the random experiment given by picking a person (randomly) from the group One might want to treat this like a continuous random variable if a lot of people are involved.

But maybe for my purposes I only care about how many people I have in much loser categories. Assume that I'm only interested in the following categories:

- People who are at most than 140 cm tall or
- people who are from 140 to 160 cm tall or
- people who are from 160 to 180 cm tall and
- people who are taller than 180 cm.<sup>25</sup>

I would like to count how many people out of the group belong to each category to construct a probability space which allows me to work out the probabilities that a randomly chosen person from that group falls into a particular category.

I may create another random variable by composing  $X$  with the function  $f: \mathbb{R} \rightarrow \mathbb{R}$  given by the following assignment.

$$x \longmapsto \begin{cases} 1 & x \leq 140 \\ 2 & 140 < x \leq 160 \\ 3 & 160 < x \leq 180 \\ 4 & 180 < x. \end{cases}$$

I can then compute the probability for the new outcomes, given by the range of the composite  $f \circ X$ , by counting how many people fall into each category and dividing by the total population count—which gives the same result as taking the original probability distribution for  $X$  and using  $f$  to translate it to the new outcomes.

We can see from the preceding example that it can be useful to take a given random variable and use a function on its possible values (here mapping actual heights to representative of some height categories) to get a different (but related) random variable that better expresses whatever we are concerned with.

**Example 4.60.** In the robot lab exercise in COMP14112 (compare Example 4.43) the orientation of the robot is viewed as an angle from 0 to 360 degrees. The orientation is a continuously varying entity, but for the purpose of that exercise this is split into 100 parts of equal size, creating a discretely valued random variable, which makes it easier to carry out calculations (Bayesian updating in that case).

The following result tells us that composing with a function  $\mathbb{R} \rightarrow \mathbb{R}$  always gives us another random variable, provided that the function is well behaved.

### Proposition 4.12

If  $X$  is a random variable and  $f: \mathbb{R} \rightarrow \mathbb{R}$  is a measurable function then

$$f \circ X$$

is a random variable.

---

<sup>25</sup>Clearly one has to think about what should happen on the borderline—let's assume here this belongs to the lower height category.

For the random variable  $f \circ X$  and an interval  $I$  in  $\mathbb{R}$  we have

$$P(f \circ X \in I) = P\{r \in \mathbb{R} \mid fr \in I\}.$$

**Optional Exercise 18.** Show that if  $X$  is a measurable function from some probability space to  $\mathbb{R}$ , and if  $f: \mathbb{R} \rightarrow [r, r']$  is measurable for the Borel probability space on the interval  $[r, r']$  then their composite  $f \circ X$  is measurable.

**Example 4.61.** Recall Example 4.51 of adding the eyes shown by two dice, which we may consider a random variable  $X$ . We might instead only wish to record whether this number is even or odd. We may express this by composing  $X$  with the following function.

$$\begin{aligned} f: \{2, 3, 4, \dots, 11, 12\} &\longrightarrow \{0, 1\} \\ x &\longmapsto x \bmod 2 \end{aligned}$$

We may now compute the probabilities for  $f \circ X$  as follows.

$$\begin{aligned} P(f \circ X = 0) &= P\{n \in \{2, 3, 4, \dots, 11, 12\} \mid n \bmod 2 = 0\} \\ &= P\{2, 4, 6, 8, 10, 12\} \\ &= \frac{1}{36} + \frac{3}{36} + \frac{5}{36} + \frac{5}{36} + \frac{3}{36} + \frac{1}{36} \\ &= \frac{18}{36} = \frac{1}{2}. \end{aligned}$$

To calculate  $P(f \circ X = 1)$  it is sufficient to note that the two probabilities have to add up to 1, and so this is also  $1/2$ .

**Example 4.62.** Recall Example 4.53 where we considered the random variable  $X$  given by counting the number of heads that appear when tossing a fair coin three times. We know that the range of  $X$  is  $\{0, 1, 2, 3\}$ , so we may think of  $X$  as a function from the original sample space to that set. The probabilities for the various outcomes are given in the following table.

0	1	2	3
$1/8$	$3/8$	$3/8$	$1/8$

Now assume we are interested only in whether the number of heads is more than one away of the number of tails, or not. The outcomes 1 and 2 satisfy that new property, and the outcomes 0 and 3 do not. Consider the following function.

$$\begin{aligned} f: \{0, 1, 2, 3\} &\longrightarrow \{1, 3\} \\ x &\longmapsto \begin{cases} 0 & x = 1 \text{ or } x = 2 \\ 1 & \text{else.} \end{cases} \end{aligned}$$

Then composing  $X$  with  $f$  gives another random variable, with range

$\{0, 1\}$ , where 0 means the number of heads is at most one different from the number of tails, and 1 means the difference is larger.

We can determine the probability for the new outcomes by adding the probabilities of the old outcomes which are mapped to it. Again we give a table that provides the probabilities for each outcome, and above each outcome of  $f \circ X$  we give the outcomes from  $X$  that are mapped to it by  $f$ .

new outcomes	0	1
old outcomes	1, 2	0, 3
probabilities	$P(X = 1) + P(X = 2)$ $= \frac{3}{8} + \frac{3}{8} = \frac{3}{4}$	$P(X = 0) + P(X = 3)$ $= \frac{1}{8} + \frac{1}{8} = \frac{1}{4}$

**Example 4.63.** In Example 4.59 the random variable  $X$  had four possible values, namely

$$\{1, 2, 3, 4\}.$$

Assume that the probabilities that a randomly chosen person from the monitor group fits into each category is given by the following table:

	1	2	3	4
$P$	1/2	1/4	1/8	1/8

We can now calculate with these probability much as if we had a discrete probability space at the start.

For example, if I want to know the probability that a member of my population is below 160cm, that is, belongs to categories 1 or 2,

$$P(X < 160) = P(f \circ X = 1) + P(f \circ X = 2) = \frac{1}{2} + \frac{1}{4} = \frac{3}{4}.$$

**Example 4.64.** Assume that I am in the situation of Example 4.59, but now I am only interested whether somebody is below 160 cm or above.

Then I can take my previous random variable, which produced the possible values

$$\{1, 2, 3, 4\},$$

and compose it with the function

$$\begin{aligned} \{1, 2, 3, 4\} &\longrightarrow \{1, 2\} \\ x &\longmapsto \begin{cases} 1 & x = 1 \text{ or } x = 2 \\ 2 & \text{else} \end{cases} \end{aligned}$$

to get a new random variable whose only values which only distinguishes between people with a height of less than or equal to 160cm, which are in category 1, and those who are taller than 160cm, which are in category 2.

**Example 4.65.** Assume we have a random variable  $X$  that has a range of values

$$\{-n, -(n-1), \dots, -2, -1, 0, 1, 2, \dots, n-1, n\}.$$

Maybe for some purposes we are not interested in the values as such, but only in how far distant they are from the mid-point, 0. This might be because we are only interested in the difference between some value and 0, but not whether that difference is positive or negative (compare also Definition 38).

By composing the random variable with the absolute function

$$\begin{aligned} |\cdot|: \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto |x|, \end{aligned}$$

we obtain a new random variable  $Y$  which takes its values in the set

$$\{0, 1, \dots, n\}.$$

To calculate probabilities for  $Y$  we have to know that

$$P(Y = i) = \begin{cases} P(X = i) + P(X = -i) & 0 \leq i \leq n \\ 0 & \text{else.} \end{cases}$$

**CExercise 80.** Recall the unfair die from Exercise 54. Take as a random variable  $X$  the number of eyes shown. Calculate the following.

- (a)  $P(X \leq 3)$ ,
- (b)  $P(X \geq 5)$ ,
- (c)  $P(4 \leq X < 6)$ ,
- (d)  $P(X \leq \pi)$ ,
- (e)  $P(X \geq 7)$ .

Now assume that the random variable  $Y$  is given by the sum of the eyes shown by two such dice. Calculate the following.

- (f)  $P(Y \leq 4.5)$ ,
- (g)  $P(Y \geq 11.5)$ .

Finally assume that we have the random variable  $Y$  and we compose it with the following function:

$$\begin{aligned} f: \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto (x - 7)^2. \end{aligned}$$

Calculate the following.

$$(h) P(f \circ Y \geq 6),$$

$$(i) P(f \circ Y \leq .5).$$

#### 4.4.4 Probability mass functions and cumulative distributions

There are many examples of random variables where we do not need to worry about all real numbers but only those that appear in the range of the random variable. We can give a graphical presentation of how the probabilities are spread over that range. It is the equivalent to a probability density function for the case where we have discrete values.

##### Definition 34: probability mass function

Let  $X$  be a random variable with a countable range, say

$$\{r_i \mid i \in \mathbb{N}\}.$$

The **probability mass function (pmf)** for  $X$  is given by

$$\begin{aligned} \{r_i \mid i \in \mathbb{N}\} &\longrightarrow [0, 1] \\ r_i &\longmapsto P(X = r_i). \end{aligned}$$

It is appropriate to think of a probability mass function as the discrete version of a probability density function.

**Example 4.66.** For the random variable that consists of assigning the total number of eyes to the throw of two dice, see Example 4.51, the pmf is given by

2	3	4	5	6	7	8	9	10	11	12
$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

This is of course the original probability distribution from Example 4.2 for one of the sample spaces discussed there—if the outcomes are already described as numbers then this is what happens.

**Example 4.67.** If we throw a coin three times, see Examples 4.53, and use the random variable that arises from assigning to each output the number of heads that appear then we get the pmf as described in that example,

0	1	2	3
$1/8$	$3/8$	$3/8$	$1/8$ .

The following is a version of Proposition 4.2 for random variables with finite range. It says that if we have a pmf for a random variable then to know the probability distribution for that random variable we merely need to know the probabilities for each of the values in that range.

### Corollary 4.13

Let  $X$  be a random variable with finite range, say  $T$ , and pmf  $p$ . Then there is a unique probability space  $(T, \mathcal{P}T, P)$  with the property that for all elements  $t \in T$  we have

$$P\{t\} = pt.$$

For this space we may calculate for all subsets  $E$  of  $T$  that

$$PE = \sum_{t \in E} pt.$$

**Proof.** This is an application of Proposition 4.2.

What this means is that if we have a probability mass function then we have a uniquely determined probability space, and so for a random variable with finite range all we need to understand the situation is the pmf. For this reason some people call a probability mass function a probability distribution.

In Section 4.2.4 the idea of a cumulative probability distribution is introduced. At this point we are ready to define that concept generally.

### Definition 35: cumulative distribution function

Given a random variable  $X$  the **cumulative distribution function (cdf) for  $X$**  is the function

$$\mathbb{R} \rightarrow [0, 1]$$

which assigns, for  $t \in \mathbb{R}$ ,

$$t \longmapsto P(X \leq t.)$$

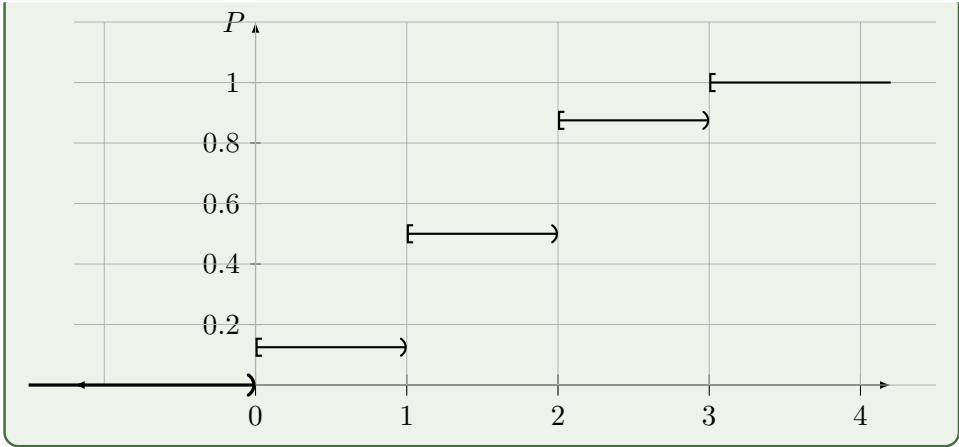

We are using here the fact that the real numbers are ordered and so it makes sense to ask for the probability that the random variable is at most some given number. In particular we can meaningfully draw the graph of this function and visualize the probability distribution in a way that we only do when the outcomes are given as numbers.

When we have a random variable which can take a finite number of values we have to draw a non-continuous function, and you may find this a bit odd at first. Look at the following example to see how that works.

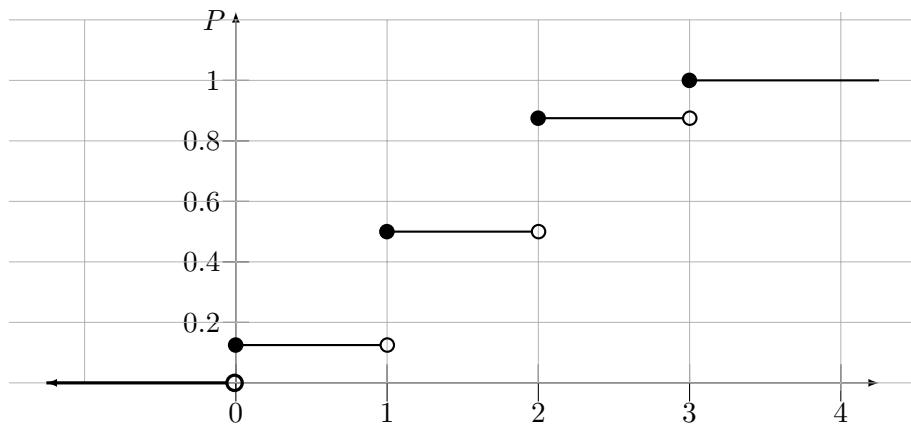

**Example 4.68.** If we look at the situation from Example 4.67 where the pmf is described in the table

0	1	2	3
1/8	3/8	3/8	1/8.

then the corresponding cdf can be drawn as follows.

Note that when drawing discontinuous functions like the above we have to specify what the value at a discontinuity is, the lower or the upper of the two lines. The convention used in the picture above is to use the interval notation, so that [ and ] mean that the point at the end of the line belongs, and ( as well as ) mean that it doesn't. An alternative way of drawing the same function is to use the following convention:

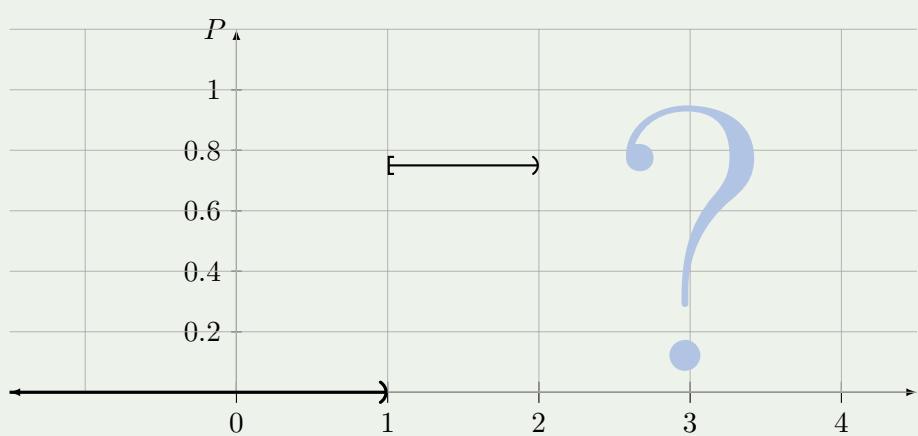

In the picture above the filled circle indicates that the endpoint of the line is included, and the unfilled circle that it is excluded.

In both pictures we can see that the functions jumps to a higher accumulated probability as the next possible value of the random variable is reached. The probability of fewer than 0 heads is 0, the probability of getting at least 0, but fewer than 1 heads is  $1/8$ , and so on.

**Example 4.69.** We return to Example 4.56, where the information given is that  $X$  is a random variable and the following is known about its probability distribution is the following:

- $P(X = 1) = 1/2$ ,
- $P(X = 2) = 1/4$ , and
- $P(X \geq 2) = 1/2$ .

This is sufficient to be able to draw some of the cdf, but there is uncertainty:

We know that the probability is 0 until the value 1 is reached, and that it rises to .5 at that point, and rising further to .75 from 2. What we don't know is when it takes on the value 1 or which values it take between .75 and 1..

**Example 4.70.** An example for the continuous case is given in Section 4.2.4 in the form of Examples 4.27 and 4.28.

Recall that in the case of a continuous random variable  $X$  with range contained in an interval  $I \subseteq \mathbb{R}$  the probability distribution is given in the form of a probability density function, say

$$g: I \rightarrow \mathbb{R}^+.$$

There are two cases.

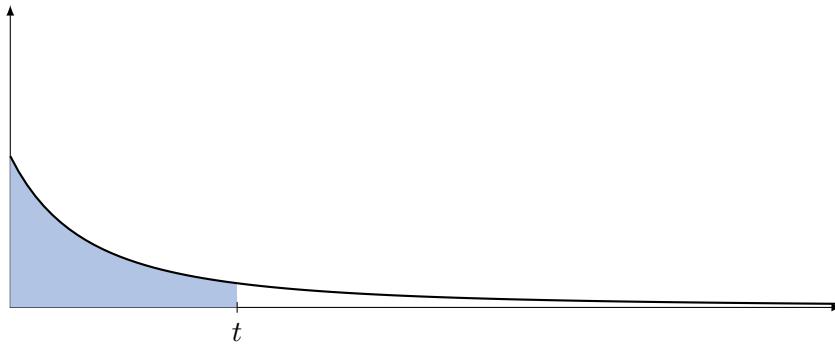

- If the interval is of the form  $(-\infty, r')$ ,  $(-\infty, r']$  or  $\mathbb{R}$  then the cdf for  $X$  is given by

$$P(X \leq t) = \begin{cases} \int_{-\infty}^t g(x) dx & t \leq r' \\ 1 & \text{else.} \end{cases}$$

- If the interval is of the form  $(r, r')$ ,  $(r, r']$ ,  $(r, \infty)$   $[r, \infty)$  then the cdf for  $X$  is given by

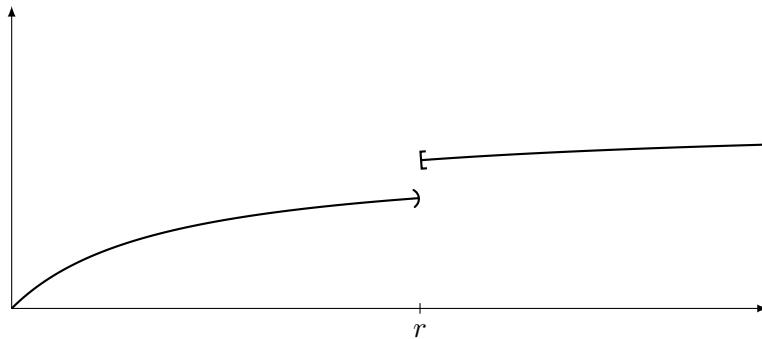

$$P(X \leq t) = \begin{cases} 0 & t \leq r' \\ \int_r^t g(x) dx & r \leq t \leq r' \\ 1 & \text{else.} \end{cases}$$

In the case below  $I$  is  $[0, \infty)$ , and we calculate the probability that  $X$  is below  $t$ .

Note that the *derivative* of a cumulative distribution function is the corresponding probability density function (which in the discrete case is the corresponding probability mass function). We have no time to discuss here exactly how the derivative is formed in the discrete case.

However there is something that is easy to see. Assume you have a random variable whose cdf  $F$  makes a jump as in the following picture.

Then it has to be the case that the probability of the random variable at the point where the jump is concerned is the difference of the two values, that is

$$P(X = r) = F(r) - \lim_{n \rightarrow \infty} F(r - \frac{1}{n}).$$

#### Proposition 4.14

Let  $X$  be a random variable. If  $P$  is its cumulative distribution function then its derivative is the corresponding probability density (mass density) function.

**CExercise 81.** For Exercise 54 consider the random variable given by the number of eyes the die shows. Give its pmf, and draw a graph for its cdf.

Then do the same with the random variable  $f \circ Y$  from Exercise 80.

**EExercise 82.** Assume that teams are regularly playing in a ‘best out of five’ series against each other, compare Exercise 52. If one assumes that performance is determined by a random process one may declare a random variable to give the number of matches Team  $A$  wins in a given series.

- (a) Describe a probability space that describes a ‘best out of five’ series.
- (b) Describe the function that underlies this random variable by writing down a mathematical function that carries out the required assignment.
- (c) For the case where team  $A$  is equally matched by Team  $B$ , give the pmf and draw a graph for its cdf.
- (d) Now assume that it is known that  $A$  wins the first match. We can now look at the random variable  $X$  conditional on this event. Describe the pmf and cdf for the resulting random variable. *Hint: Because the event  $A$  is part of the original probability space, but cannot be formulated for the outcomes of the random variable  $X$ , you cannot use the usual formula for conditional probabilities but have to analyse each case anew. If you are finding this part hard then looking ahead to Example 4.73 may help.*

#### 4.4.5 Conditional probabilities for random variables

Recall that there is no example for conditional probabilities in the continuous case in Section 4.3 above. The reason for this is that describing the probability density function for the general case, where we may make no assumptions about the possible outcomes, requires mathematical techniques beyond this course unit.

However, this is feasible once we restrict ourselves to random variables, where we know that the outcomes are elements of  $\mathbb{R}$ . We revisit the idea of conditional probabilities, now confined to random variables. You can see below that in that case the definition for the continuous case is the same as that for the discrete one.

##### The conditional probability density function

Recall that given two events  $A$  and  $B$ , where  $PB \neq 0$ , the conditional probability of  $A$  given  $B$  is defined as

$$P(A | B) = \frac{P(A \cap B)}{PB}.$$

If  $X$  is a random variable with probability distribution function  $F$  then we may define the conditional distribution of  $X$  given the event  $B$  as

$$P(X \leq r | B) = \frac{P((X \leq r) \cap B)}{PB}.$$

There is a conditional probability density function, which is once again the derivative of the corresponding distribution. The probability that the conditionally distributed random variable falls into a given interval is then the integral over that derivative over the given integral.

If  $X$  is a discrete random variable with pmf  $p$  then given an event  $B$  with  $PB \neq 0$  we can calculate the pmf  $q$  of the random variable

$$(X | B), \quad X \quad \text{given} \quad B,$$

by setting, for  $r$  in the range of  $X$ ,

$$qr = \begin{cases} \frac{P(X = r)}{PB} & r \in B \\ 0 & \text{else.} \end{cases}$$

In other words, if we know that  $B$  happens, and  $r$  is a possible result of  $X$  not in  $B$ , then it has the probability 0, and otherwise the probability is adjusted by dividing through  $PB$  as expected.

**Example 4.71.** We return to Example 4.53. The pmf for the random variable  $X$  which gives the number of heads when a coin is tossed three times is as follows.

0	1	2	3
1/8	3/8	3/8	1/8.

Let the event  $A$  be that the result heads occurs at least once among the three tosses. The probability of  $A$  is  $PA = 7/8$ . We may calculate

$$P((X = i) | A) = \frac{P((X = i) \cap A)}{P(A)},$$

where

$$P((X = i) \cap A) = \begin{cases} P(X = i) & i \in A \\ 0 & \text{else.} \end{cases}$$

Hence the pmf of

0	1	2	3
0	3/7	3/7	1/7.

If  $B$  is the event that the number of heads is even then  $PB = 1/2$  and the pmf of

0	1	2	3
1/4	0	3/4	0.

We look at the continuous case. Let  $X$  be a random variable with range  $\mathbb{R}$  and probability distribution  $f$ , let  $r$  be in  $\mathbb{R}$ , and assume that  $B$  is the event

$$B = (X \leq r).$$

We may calculate

$$PB = P(X \leq r) = \int_{-\infty}^r f(x) dx.$$

We might then wonder how to calculate, for  $s \in \mathbb{R}$ ,

$$P(X \leq s | B).$$

What we do know is that if we have a probability density function  $g$  for the resulting random variable we can calculate this probability as

$$\int_{-\infty}^s g(x) dx.$$

We can work out what the probability density function, say  $g$ , should do: If the argument is not in  $B$  it should return 0, and otherwise it should return the probability of  $x$  adjusted by the probability of  $B$ . Assuming that the

probability of  $B$  is non-zero,  $g$  is given by

$$g: \mathbb{R} \longrightarrow \mathbb{R}^+$$

$$x \longmapsto \begin{cases} \frac{fx}{\int_{-\infty}^r fxdx} & x \leq r \\ 0 & \text{else.} \end{cases}$$

In the general case, where we make no assumptions about the shape of  $B$ , we merely assume that the probability of  $B$  is not zero. The probability distribution  $g$  of the random variable

$$Y = (X | B)$$

is given by

$$g: \mathbb{R} \longrightarrow \mathbb{R}^+$$

$$x \longmapsto \begin{cases} \frac{fx}{PB} & x \in B \\ 0 & \text{else.} \end{cases}$$

Note that the range of  $Y$  is included in  $B$ .

**Example 4.72.** If we return to Example 4.28 we have a random variable given by the time until the geyser next erupts. The probability density function is

$$f: [0, 90] \longrightarrow [0, 1]$$

$$x \longmapsto \frac{1}{90}.$$

Consider the event  $B$  that the geyser hasn't erupted in the 30 minutes we've already waited for it. We may calculate the probability of  $B$  occurring by calculating the probability that the geyser does erupt in the first 30 minutes, and deducting that from one. The probability that the geyser erupts between minute 0 and 30 is

$$\int_{30}^{90} fxdx = \int_0^{30} \frac{1}{90} dx = \left[ \frac{x}{90} \right]_0^{30} = \frac{30}{90} - 0 = \frac{1}{3},$$

so

$$PB = 1 - \frac{1}{3} = \frac{2}{3}.$$

The probability density function  $g$  of the random variable

$$(X | B)$$

is then given by

$$g: [0, 90] \longrightarrow [0, 1]$$

$$x \longmapsto \begin{cases} 0 & 0 \leq x \leq 30 \\ \frac{1}{60} & \text{else.} \end{cases}$$

The examples we have considered here only work if the event on which we are conditioning can be expressed in terms of outcomes of the random

variable in question. Sometimes we wish to condition on an event that can only be formulated in the original probability space, see Exercise 82 for an example. In that case the various conditional probabilities have to be calculated more painstakingly since we cannot apply the formulae derived above. We return to this idea in Section 4.4.6 after considering one more example.

**Example 4.73.** We return to the random variable  $X$  which counts the number of heads when tossing a coin three times, see Example 4.53, and contrast with Example 4.71. The pmf of  $X$  is given by the following table.

0	1	2	3
1/8	3/8	3/8	1/8.

Assume we wish to condition this random variable on the event  $C$  that the first toss is heads. The given pmf does not help us in calculating the pmf of  $(X | C)$ . Instead we have to start over from the original probability space. We analyse the possible values of  $X$  and the probabilities with which they occur. Assume the first toss is heads. The possible numbers of heads among the three tosses are as follows.

- 0. This cannot occur.
- 1. This means the toss must be  $HTT$ . This occurs with probability  $1/4$ .
- 2. This means the toss is  $HHT$  or  $HTH$ . This occurs with probability  $1/2$ .
- 3. This means the toss is  $HHH$ . This occurs with probability  $1/4$ .

Hence the pmf of

$$P(X | C) \quad \text{is} \quad \begin{array}{c|c|c|c} 0 & 1 & 2 & 3 \\ \hline 0 & 1/4 & 1/2 & 1/4. \end{array}$$

Note that it is also possible to perform Bayesian updating for random variables: In the case of a discrete random variable, the update procedure is just as described in Section 4.3.4. If the random variable is continuous then instead of updating the pmf by adjusting all the individual values we have to update the probability density function. Spelling out the resulting definition of the new probability density function goes beyond this course unit.

### One random variable depending on another

The material in this subsection is not examinable. You may want to return to it if you ever have to cope with a situation where one random variable depends on another.

Recall Example 4.37, where we were wondering about how to describe the probability density function for the location or a fox whose behaviour is influenced by the location of a lynx (if the latter is close enough).

What we have there is one random process, describing the movements of the fox, conditional on another random process, namely the movement of the lynx.

We can only do this in the situation where we have a *joint distribution*, that is, a probability distribution, or a density function/pmf, that describes the combined probability.

It is then the case that if  $f$  is the joint density function for random variables  $X$  and  $Y$ , we can derive density functions for  $X$  and  $Y$ , namely

- The probability density function for  $X$  is<sup>26</sup>

$$\int_{-\infty}^{\infty} f(x, y) dy,$$

- while that for  $Y$  is

$$\int_{-\infty}^{\infty} f(x, y) dx.$$

In this situation we can look at the case of the density function  $g$  for  $X$  given ( $Y = s$ ), for some  $s \in \mathbb{R}$ . We get

$$gx = \frac{f(x, s)}{\int_{-\infty}^{\infty} f(x, s) dy}.$$

If instead we are interested in the probability distribution for  $X$  given

$$(s \leq Y \leq s'),$$

we have

$$P(X = r \mid s \leq Y \leq s') = \frac{\int_{-\infty}^r \left( \int_s^{s'} f(x, y) dy \right) dx}{\int_s^{s'} \left( \int_{-\infty}^{\infty} f(x, y) dx \right) dy}.$$

If  $X$  and  $Y$  are discrete random variables then we can look at their joint pmf. This is a function that, given

- a value  $r$  from the range of  $X$  and
- a value  $s$  from the range of  $Y$ ,

returns the probability

$$P(X = r \text{ and } Y = s).$$

**Example 4.74.** We return to the example of tossing a coin three times, see Example 4.53. The pmf of the random variable  $X$ , which counts the number of heads, is

0	1	2	3
1/8	3/8	3/8	1/8.

The random variable  $Y$ , which records the absolute of the difference between the number of heads and tails, has a pmf given by the following table.

---

<sup>26</sup>You can calculate with these integrals by treating the other variable as if it were a parameter, that is, you integrate the first expression for  $y$  and treat  $x$  as if it was a number. You swap the treatment of the two variables for the second expression.

	1	3	
	6/8	2/8.	

The joint pmf of  $X$  and  $Y$  is given by the following table.

$Y \setminus X$	0	1	2	3	
1	0	3/8	3/8	0	
3	1/8	0	0	1/8	

### Independent random variables

When we have two random variables which are independent from each other it becomes easier to calculate with both.

#### Definition 36: independent random variables

Two random variables  $X$  and  $Y$  are *independent* if and only if it is the case that for all elements of the Borel  $\sigma$  algebra  $E$  and  $E'$  we have that

$$P(X \in E \text{ and } Y \in E') = P(X \in E) \cdot P(Y \in E').$$

In particular this means that

- if  $X$  is a random variable with density function  $f$  and
- $Y$  is a random variable with density function  $g$  then

the joint density function for  $X$  and  $Y$  is given by

$$(x, y) \longmapsto f_x \cdot g_y.$$

We need this information when we wish to look at situation where we have several random variables, for example the failure of a number of pieces of equipment. This is easier if we assume that the failure of one is independent from the failure of the others but this assumption is only justified if we can exclude factors that would affect more than one piece of equipment, such as a power surge at some location.

**Example 4.75.** We have already seen an example of this. When we look at the random variable  $X$  which gives us the number of eyes shown by the red die, and the random variable  $Y$  which gives us the number of eyes shown by the blue die, then their joint pmf is given as follows.

$i \setminus j$	1	2	3	4	5	6	
1	1/36	1/36	1/36	1/36	1/36	1/36	
2	1/36	1/36	1/36	1/36	1/36	1/36	
3	1/36	1/36	1/36	1/36	1/36	1/36	
4	1/36	1/36	1/36	1/36	1/36	1/36	
5	1/36	1/36	1/36	1/36	1/36	1/36	
6	1/36	1/36	1/36	1/36	1/36	1/36	

**Exercise 83.** Are the two random variables  $X$  and  $Y$  from Example 4.74 independent? Justify your answer.

**EExercise 84.** Assume that you are tasked by your boss with making sure that you have enough servers that the probability of no server being currently online is at most 1% for the entire year. Because you are able to place your servers at separate locations you are allowed to assume that one server failing will have no effect on the other servers.

(a) Assume that the chance of one of your servers failing in a given year is .05. How many servers do you need to comply with your boss's demand? How much safety do you get out of an extra server?

(b) Assume that the probability of one of your servers failing has the probability density function<sup>27</sup>  $f$  given by

$$f: [0, 365] \longrightarrow [0, 1]$$

$$x \longmapsto \frac{x^2}{2 \cdot 365^3},$$

which we need to consider from  $x = 0$  to  $x = 365$  to cover the year. In other words, the probability that the server will have failed by the end of the year is given by the integral, from 0 to 365, over the given density function. How many servers do you have to buy and install to ensure that the probability of one of them having failed is below the threshold you were given?

#### 4.4.6 Expected value and standard deviation

One of the motivations for introducing the notion of random variables is the ability to form averages.

##### Expected value

**Example 4.76.** Returning to the example of the number of heads when tossing a coin three times, Example 4.67, you may wonder what the average number of heads might be. This case is so simple that you can probably guess the answer, but in more complicated situations you will want to carry out analogous calculations. If we weigh each possible outcome by its probability then this number is given by

$$0 \cdot \frac{1}{8} + 1 \cdot \frac{3}{8} + 2 \cdot \frac{3}{8} + 3 \cdot \frac{1}{8} = \frac{0+3+6+3}{8} = \frac{12}{8} = \frac{3}{2},$$

so on average the number of heads is 1.5, which in this simple case you may have been able to guess. Note that if you wanted to bet on the outcome of this experiment then it does not make sense to bet the expected value since it cannot occur.

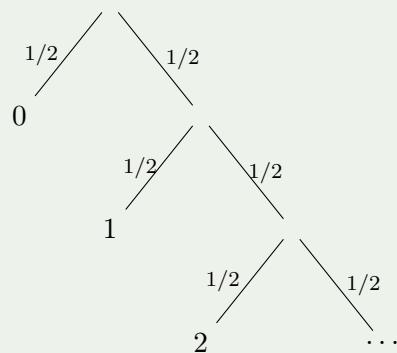

We look at more interesting examples. Note that solving the following two examples requires knowledge beyond this course unit—it is included here to give you an idea of how powerful the idea is.

---

<sup>27</sup>I'm not claiming this is a realistic density function, but hopefully it's not too bad to calculate with.

**Example 4.77.** Assume that we have strings which are generated in a random way, in that after each key stroke, with a probability of  $1/2$ , another symbol is added to the string. We would like to calculate the average length of the strings so created. Before we can do this we have to specify when the random decision starts: Are all strings non-empty, or is there a chance that no symbol is ever added? We go for the latter case, but the calculation for the former is very similar.

As is often the case when picturing a step-wise process we can draw a tree that describes the situation. At each stage there is the random decision whether another symbol should be added or not. We give the length of each generated string.

What this means is that we have a random variable, namely the length of the generated string, and we can see that its probability mass function has the first few values given by the following table.

0	1	2	3	4
$1/2$	$1/4$	$1/8$	$1/16$	$1/32$

More precisely the pmf is given by the function

$$\begin{aligned} \mathbb{N} &\longrightarrow \mathbb{R} \\ n &\longmapsto \frac{1}{2^{n+1}}. \end{aligned}$$

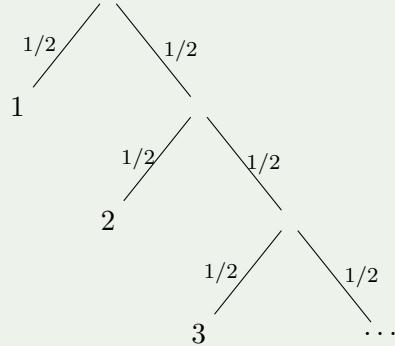

What is the average string length? The idea is that we should give each possible length the probability that it occurs. This means that we should calculate

$$0 \cdot \frac{1}{2} + 1 \cdot \frac{1}{4} + 2 \cdot \frac{1}{8} + \dots = \sum_{n \in \mathbb{N}} n \cdot \frac{1}{2^{n+1}}.$$

With a bit more mathematics than we can teach on this unit it may be calculated<sup>28</sup> that this required number is 1. So certainly when producing strings in this way we don't have to worry about there being a lot of long ones! But note that we have described a process for producing potentially infinite strings (with a probability of 0), and the power of the methods we use here is such that we can still calculate the average.

We say more about how to cope with situations where we have to compute an infinite sum in Section 4.4.6.

**Example 4.78.** Assume we are tossing a coin until we get heads for the first time, and then we stop (compare Exercise 56 and Example 4.26). We wonder what the average number of coin tosses is. Again it makes sense to draw a tree.

This is quite similar to the previous example! The pmf for this random variable is given by

$$\begin{aligned} \mathbb{N} &\longrightarrow \mathbb{R} \\ n &\longmapsto \frac{1}{2^n}. \end{aligned}$$

The expected value is

$$\sum_{n \in \mathbb{N}} n \cdot \frac{1}{2^n} = 2.$$

Again calculating such expected values is not part of this unit, but it gives you one motivation why mathematicians care about what happens if infinitely many numbers are added up.

We say more about how to cope with situations where we have to compute an infinite sum in Section 4.4.6, in particular Example 4.85 is relevant.

What is it that we have calculated in these examples?

### Definition 37: expected value

Let  $X$  be a random variable with probability density function  $p$ . Then the **expected value of  $X$** ,  $E(X)$ , is given by

$$E(X) = \int_{-\infty}^{\infty} x \cdot p(x) dx.$$

Note that this definition does allow for the possibility that  $E(X)$  is infinite. This can never occur if  $X$  is a discrete random variable with a finite range, but in the other cases this is a possibility. Calculating with infinities is beyond the scope of this unit, and all the examples we study give a finite result.

Note that if  $X$  is a discrete random variable with range

$$\{r_i \mid i \in \mathbb{N}\},$$

---

<sup>28</sup>In mathematical parlance, we have defined a series whose limit is 1.

then its expected value is

$$E(X) = \sum_{i \in \mathbb{N}} r_i \cdot P(X = r_i).$$

This means that if  $X$  is a discrete random variable with finite range

$$\{r_1, r_2, \dots, r_n\},$$

then its expected value is

$$\begin{aligned} E(X) &= r_1 P(X = r_1) + r_2 P(X = r_2) + \dots + r_n P(X = r_n) \\ &= \sum_{i=1}^n r_i P(X = r_i). \end{aligned}$$

Note that in the discrete case, the expected value need not be in the range of  $X$ . In Example 4.76 the expected value is 1.5 heads in 3 tosses of a coin, which clearly is not a valid result of tossing a coin three times.

Further note that even if the expected value is a possible outcome it need not in itself be particularly likely.

**Example 4.79.** Assume we are playing a game with a deck consisting of four aces and the kings of spades and hearts,

$$\{A\clubsuit, A\spadesuit, A\heartsuit, A\diamondsuit, K\spadesuit, K\heartsuit\}.$$

We each draw a card from the pack. If one of us has an ace and the other a king, the holder of the ace gets two pence from the other player. If we both have an ace, then if one of us has a black ace  $A\clubsuit$  or  $A\spadesuit$  then he gets three pence from the other player. If we have aces of the same colour neither of us gets anything. If both of us have a king then the holder of the black king gets one penny from the other player.

We look at the random variable formed by the number of pence gained or lost by one of the players (since the rules are symmetric it does not matter which player we pick). Its range and pmf are given in the following table.

-3	-2	-1	0	1	2	3
2/15	4/15	1/30	2/15	1/30	4/15	2/15

We calculate the expected pay-off. It is

$$\frac{1}{30}(-3 \cdot 4 + (-2) \cdot 8 + (-1) \cdot 1 + 0 \cdot 4 + 1 \cdot 1 + 2 \cdot 8 + 3 \cdot 4) = 0.$$

We could have saved us this calculation by making the following deductions: The game is completely symmetric, and wins for one player are paid for by the other.<sup>29</sup> So if one player were to expect a gain the other player would have to expect a loss to make up for that game, but the rules are exactly the same for both.

We note that the expected value 0 does not occur with a particularly high probability.

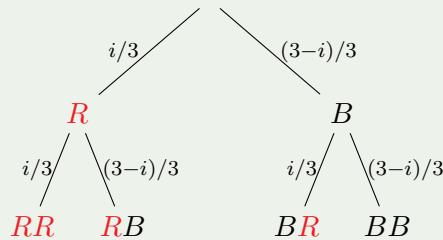

---

<sup>29</sup>This is a *zero-sum game* in the parlance of game theory.

Also note that the expected value does not have to be halfway between the extremes of the possible outcomes. This is illustrated (among other things) in the following example, where we calculate the average of an average to show that it is possible to have several layers of random variables, which still allow us to calculate an overall expected value.

**Example 4.80.** For a more down to earth example let us revisit Example 4.41. There we are faced with 4 possibilities regarding which situation we are in (given by the number of red socks in the bag). This gives us an opportunity to look at an expected value for different probability distributions.

Here is a tree that describes the drawing of two socks (with replacement) from a bag that contains  $i$  red socks from a total of 3 socks.

We have here a random variable which maps the outcomes from this tree to the number of red socks drawn. Hence it maps  $RR$  to 2, the outcomes  $RB$  and  $BR$  to 1 and the outcome  $BB$  to 0. The pmf of this random variable is

	2	1	0
$\frac{i^2}{9}$	$2\frac{i(3-i)}{9}$	$\frac{(3-i)^2}{9}$	

Hence the expected value for the number of socks is

$$2\frac{i^2}{9} + 2\frac{i(3-i)}{9} = \frac{2i^2 + 6i - 2i^2}{9} = \frac{6i}{9}.$$

So the expected value in each case is

i	0	1	2	3
$E(X)$	0	$2/3$	$4/3$	2

Note how the expected value varies with the underlying situation, and note that in none of the cases we get as the expected value the halfway point between the two extremes 0 and 2.

We can use these expected values to calculate an *overall expected value* based on our current estimate for the true probability distribution.

At the beginning, the probability of the possible outcomes,

$$\{0, 1, 2, 3\}$$

is equal,  $1/4$  for each. If we draw two socks (returning the sock to the bag after each draw) then we would expect to draw one red and one black sock on average.

After the first update the pmf is

0	1	2	3
0	$1/6$	$1/3$	$1/2$

If we want the expected value based on our current knowledge, which is given by the current distribution, then we should form an average where each of the previously calculated expected values is weighted by the probability that we think it's the correct one, giving an overall expected value of

$$0 \cdot 0 + \frac{2}{3} \cdot \frac{1}{6} + \frac{4}{3} \cdot \frac{1}{3} + 2 \cdot \frac{1}{2} = \frac{2+8+18}{18} = \frac{28}{18} = 1.\bar{5}.$$

**Example 4.81.** For a simple continuous example we return to the random variable that describes the amount of time until a geyser erupts from Examples 4.28 and 4.72. The expected time we have to wait until the geyser erupts is

$$\int_0^{90} \frac{x}{90} dx = \left[ \frac{x^2}{2 \cdot 90} \right]_0^{90} = \frac{90^2}{2 \cdot 90} - 0 = 45,$$

which tells us that we have to wait 45 minutes on average as expected.

**Optional Exercise 19.** For the expected value given at the end of the previous example, what is the underlying random variable? Give its range and its pmf.

**CExercise 85.** You are invited to play the following game: There are three cards:

- One is black on both sides,
- one is red on both sides,
- one is black on one side and red on the other.

You and another person pay one pound each into a kitty. The three cards are put into a bag and mixed together. Without looking into a bag you draw a card. You pull it out of the bag in a way that only the upper side can be seen, and you place it on the table. The card is red on the side you can see.

The other player bets that the card has the same colour on the hidden side as is showing. You're unsure whether you should bet on it having a different colour on the other side. The other player points out that it can't be the card that is black on both sides, so you have a 50-50 chance.

The winner of the bet is to get the two pounds put into the kitty at the start. Should you accept this as a fair game, or should you ask

for your pound back? Answer this question by calculating the expected value of the amount you have to pay.

### Using conditioning to calculate expected values

Recall Example 4.78 where we determined the expected number of coin tosses until we get heads for the first time. If we use the definition of the expected value then we have to calculate with an infinite sum to find that number.

We can use conditional probabilities to help with this situation, see Section 4.4.5 for a general account of the probability distribution of a random variable conditioned on an event. In this section we are concerned with how to calculate the expected value of such a random variable.

We first look at the general case. Let  $X$  be a random variable with probability density function  $f$  and let  $B$  be an event with non-zero probability which is a subset of  $\mathbb{R}$ . Then

$$E(X | B) = \int_B \frac{1}{PB} \cdot x \cdot f(x) dx = \frac{1}{PB} \int_B x \cdot f(x) dx,$$

Note that the integral looks similar to the integral defining the expected value of  $X$ , but we cannot use one to calculate the other since the areas over which we integrate differ.

**Example 4.82.** In Example 4.81 we calculate the expected value of the time we have to wait when we visit the geyser from Example 4.28, which is 45 minutes. In Example 4.72 we give a probability distribution conditioned on the event  $B$  that the geyser has not erupted in the last thirty minutes. Applying the ideas above we calculate the expected value of

$$(X | B),$$

using the probability density function  $g$  calculated in Example 4.72, which is

$$\begin{aligned} g: [0, 90] &\longrightarrow [0, 1] \\ x &\longmapsto \begin{cases} 0 & 0 \leq x \leq 30 \\ \frac{1}{60} & \text{else.} \end{cases} \end{aligned}$$

We have

$$\begin{aligned} E(X | B) &= \int_{-\infty}^{\infty} gy dy = \int_{30}^{90} \frac{x}{60} dx = \left[ \frac{x^2}{2 \cdot 60} \right]_{30}^{90} \\ &= \frac{1}{2 \cdot 60} (90^2 - 30^2) = \frac{1}{120} \cdot 7200 = 60. \end{aligned}$$

This may strike you as unexpected: When we arrived we thought we might have to wait 45 minutes, but knowing that the geyser has not erupted for 30 minutes so far means that if we look at the conditional random variable we have to adjust our expectations to be rather more pessimistic!

In the discrete case the expected value can be expressed as follows. Let the range of  $X$  be given by

$$\{r_i \mid i \in \mathbb{N}\},$$

and let  $B$  be an event with non-zero probability. Then

$$E(X \mid B) = \frac{1}{P_B} \sum_{i \in \mathbb{N}, r_i \in B} r_i P(X = r_i).$$

If we further reduce this to the case where the range of  $X$  is finite, then we may calculate the elements of the finite set

$$\{r \in B \mid r \text{ is in the range of } X\}, \quad \text{say} \quad \{r_1, r_2, \dots, r_n\}$$

and then we have

$$E(X \mid B) = \frac{1}{P_B} (r_1 P(X = r_1) + r_2 P(X = r_2) + \dots + r_n P(X = r_n)).$$

**Example 4.83.** Recall the random variable  $X$  from Example 4.53 of the number of heads when tossing a coin three times. We calculate its expected value as 1.5 in Example 4.83 and we calculate its conditional pmf for the event  $A$  that there is at least one head in Example 4.71. The expected value of

$$(X \mid A),$$

whose pmf is (as per Example 4.71)

0	1	2	3
0	3/7	3/7	1/7.

is given by

$$E(X \mid A) = \frac{1}{7}(1 \cdot 3 + 2 \cdot 3 + 3 \cdot 1) = \frac{12}{7}.$$

Alternatively we can use the formula from above to carry out this calculation based on the pmf of  $X$ , which is given by

0	1	2	3
1/8	3/8	3/8	1/8.

The calculation then is

$$E(X \mid A) = \frac{8}{7} \cdot \frac{1}{8}(1 \cdot 3 + 2 \cdot 3 + 3 \cdot 1) = \frac{12}{7}.$$

**Exercise 86.** For the random variable of tossing a coin three times, and the event  $B$  from Example 4.71 calculate the expected value of the random variable  $Y = (X \mid B)$ .

Note that above we assume that the event on which we are conditioning is an event that can be formulated regarding the outcomes of the given random variable  $X$ . What happens quite frequently is that one wishes to condition on an event that can only be formulated in the original probability space. In those cases there is no way of applying the formulae derived above.

**Example 4.84.** Consider the random variable from Example 4.53 where we toss a coin three times. We might wish to condition over the event  $C$  that the first toss is heads. This is not something we can formulate by only referring to outcomes of this random variable. The pmf for the random variable  $(X | C)$  is carried out in Example 4.73, where it is given as follows.

0	1	2	3
0	1/4	1/2	1/4

With the help of that pmf we can calculate the expected value

$$E(X | C) = \frac{1}{4}(0 \cdot 0 + 1 \cdot 1 + 2 \cdot 2 + 3 \cdot 1) = \frac{8}{4} = 2,$$

but we cannot calculate this expected value from the expected value of  $X$ .

There is a useful technique for calculating expected values of random variables when it is easier to calculate expected values for conditioned versions of that random variable. Applications of the following result follow below.

### Proposition 4.15

Let  $X$  be a random variable over the probability space  $(S, \mathcal{E}, P)$  and assume that we have pairwise disjoint events  $B_1, B_2, \dots, B_n$  such that

$$S \subseteq B_1 \cup B_2 \cup \dots \cup B_n.$$

Then

$$EX = E(X | B_1) \cdot PB_1 + E(X | B_2) \cdot PB_2 + \dots + E(X | B_n) \cdot PB_n.$$

**Proof.** Proving the general case goes beyond what we cover on this course unit. For the discrete case, let us assume that the range of  $X$  is given by

$$\{r_i \in \mathbb{R} \mid i \in \mathbb{N}\}.$$

Then

$$\begin{aligned}
& EX \\
&= \sum_{i \in \mathbb{N}} r_i P(X = r_i) && \text{def } EX \\
&= \sum_{i \in \mathbb{N}} r_i (P(X = r_1 | B_1) PB_1 + P(X = r_i | B_2) PB_2 \\
&\quad + \cdots + P(X = r_i | B_n) PB_n) && \text{tot prob} \\
&= \sum_{i \in \mathbb{N}} r_i P(X = r_1 | B_1) PB_1 + \sum_{i \in \mathbb{N}} r_i P(X = r_i | B_2) PB_2 \\
&\quad + \cdots + \sum_{i \in \mathbb{N}} r_i P(X = r_i | B_n) PB_n \\
&= PB_1 \sum_{i \in \mathbb{N}} r_i P(X = r_1 | B_1) + PB_2 \sum_{i \in \mathbb{N}} r_i P(X = r_i | B_2) + \\
&\quad \cdots + PB_n \sum_{i \in \mathbb{N}} r_i P(X = r_i | B_n) \\
&= E(X | B_1) PB_1 + E(X | B_2) PB_2 + \cdots + E(X | B_n) PB_n.
\end{aligned}$$

This completes the proof.

We show how to use this idea to calculate expected values of a random variable conditioned over an event of the original probability space.

**Example 4.85.** We are interested in the random variable  $X$  which gives the number of tosses of a coin until we see heads for the first time. We would like to calculate its expected value  $EX$ . Note that in Example 4.78 we required an infinite sum to find that value. Here we give an alternative method that does work without infinite sums.

Since the probability of the first toss being heads is  $1/2$ , and since this is also the probability of the first toss being tails, we may use the proposition above to write

$$EX = \frac{1}{2}E(X | \text{first toss } H) + \frac{1}{2}E(X | \text{first toss } T).$$

We look at the two expressions on the right hand side.

- If the first toss is heads then we may stop tossing our coin, and so then the expected value of  $X$ , conditional on the first toss being heads, is 1.
- If the first toss is tails then it is as if we had not started to toss at all, and the expected value of  $X$ , conditional on that event, is one more than the expected value of  $X$ .

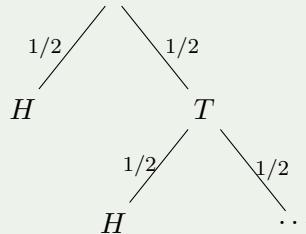

From these considerations we get

$$EX = \frac{1}{2} \cdot 1 + \frac{1}{2}(1 + E(X)) = 1 + \frac{1}{2}EX.$$

We can treat this as an equation in  $EX$  and solve it to give

$$EX = 2.$$

For an alternative way of looking at the situation we draw the appropriate tree.

we can see that below the node labelled  $T$  in the picture, we have another copy *of the same tree*. In other words, the tree branches to

- $H$ , where it ends or
- $T$ , below which another copy of the whole tree appears.<sup>30</sup>

Because a copy of the infinite tree appears within itself we can use the trick of establishing an equation in  $EX$  above.

In general we can often avoid having to calculate with infinite sums by using similar techniques. Assume we have a random experiment which has a particular result  $s$  with property  $p$ , and another result  $s'$  with property  $1 - p$  and that previous experiments have no effect on subsequent ones. We are interested in the expected value of the random variable  $X$  of how many times we have to repeat the experiment to get the second outcome we can see that we have

$$\begin{aligned} EX &= (1 - p)E(X \mid \text{first outcome } s') + p(1 + E(X \mid \text{first outcome } s)) \\ &= (1 - p) \cdot 1 + p(1 + E(X \mid \text{first outcome } s)) \\ &= (1 - p) + p(1 + EX) \\ &= 1 + pEX. \end{aligned}$$

This means that in this situation we get that

$$EX = \frac{1}{1 - p}.$$

**Example 4.86.** Assume we have a coin that shows head with probability  $p$ , and tails with probability  $1 - p$ . Let  $X$  be the random variable of the number of coin tosses required until we see heads for the first time.

In Example 4.85 we calculate the expected value of  $X$  in the case of a fair coin. Here we want to establish that it is possible to condition on the two disjoint events, namely that the first toss gives heads, or that the first toss gives tails, and use those to express the expected value of  $X$ .

---

<sup>30</sup>This can only work with infinite structures.

$$\begin{aligned}
EX &= \sum_{i \in \mathbb{N}} i P(X = i) && \text{def } EX \\
&= \sum_{i \in \mathbb{N}} i (P(X = i \mid \text{fst toss } H) P(\text{fst toss } H) \\
&\quad + P(X = i \mid \text{fst toss } T) P(\text{fst toss } T)) && \text{law of tot prob} \\
&= \sum_{i \in \mathbb{N}} i P(X = i \mid \text{fst toss } H) P(\text{fst toss } H) \\
&\quad + \sum_{i \in \mathbb{N}} i P(X = i \mid \text{fst toss } T) P(\text{fst toss } T) \\
&= E(X \mid \text{fst toss } H) P(\text{fst toss } H) \\
&\quad + E(X \mid \text{fst toss } T) P(\text{fst toss } T) \\
&= E(X \mid \text{fst toss } H)p + E(X \mid \text{fst toss } T)(1 - p).
\end{aligned}$$

This idea generalizes to similar experiments with several outcomes. Assume there are  $n$  possible outcomes

$$s_1, s_2, \dots, s_n$$

and that

- for  $1 \leq i \leq n - 1$  outcome  $s_i$  occurs with probability  $p_i$  and
- outcome  $s_n$  occurs with probability  $1 - (p_1 + p_2 + \dots + p_{n-1})$ .

Then the expected number of times we have to repeat the experiment to get outcome  $s_n$  has to satisfy the equation

$$\begin{aligned}
EX &= 1 - (p_1 + p_2 + \dots + p_{n-1}) + p_1(1 + E(X \mid 1st \ s_1)) \\
&\quad + \dots + p_{n-1}(1 + E(X \mid 1st \ s_n)) \\
&= 1 + (p_1 + p_2 + \dots + p_{n-1})EX
\end{aligned}$$

and so we must have

$$EX = \frac{1}{1 - (p_1 + p_2 + \dots + p_{n-1})}.$$

**EExercise 87.** Assume you have a fair coin.

- What is the expected number of tosses until you have two heads in a row for the first time?
- What is the expected number of tosses until you have heads immediately followed by tails for the first time?
- Assume you are invited by one of your friends to play the following game: A coin is tossed unto either
  - two heads occur in a row for the first time or
  - we have heads immediately followed by tails for the first time.

In the first case you get 6 pounds and in the second case you have to pay the other player 5 pounds. Should you play this game?

*Hint: Use the same idea as in Example 4.85.*

### Properties of expected values

We know from Proposition 4.12 that we may compose a random variable with a (measurable) function from its range to (a subset of)  $\mathbb{R}$  and that gives another random variable. But in general there is no easy formula for the expected value in that situation:

Composing with a function will lead to a different probability density function, and forming the integral over that cannot in general be expressed in terms of the integral giving the expected value for the original random variable. Even if the given random variable is discrete we do not get a simple formula: Assume that  $f$  is a measurable function from the range of a random variable  $X$  to a subset of  $\mathbb{R}$ . Then the new random variable has an expected value of

$$E(f \circ X) = \sum_{r \in \text{range}(f \circ X)} r \cdot P(f \circ X = i).$$

This indicates that there is no easy to calculate the expected value of  $f \circ X$  from that of  $X$ . This situation only changes when  $f$  is a very simple function.

**Exercise 88.** Let  $X$  be a random variable; consider the following function:

$$\begin{aligned} f: \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto 1. \end{aligned}$$

Calculate the expected value of the random variable  $f \circ X$ .

If the function  $f$  is a linear function (compare Chapter 0) then we can compute the expected value of  $f \circ X$  from that of  $X$ . Assume we have a discrete random variable  $X$ , with range

$$\{r_i \in \mathbb{R} \mid i \in \mathbb{N}'\}.$$

Let  $a$  and  $b$  be real numbers. We can compose  $X$  with the function

$$\begin{aligned} \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto ax + b. \end{aligned}$$

What is the expected value of the resulting random variable? We can calculate

$$\begin{aligned} E(aX + b) &= \sum_{i \in \mathbb{N}} (a \cdot r_i + b) \cdot P(aX + b = a \cdot r_i + b) \\ &= \sum_{i \in \mathbb{N}} (a \cdot r_i + b) \cdot P(X = r_i) \\ &= \sum_{i \in \mathbb{N}} a \cdot r_i \cdot P(X = r_i) + b \cdot P(X = r_i) \\ &= a \sum_{i \in \mathbb{N}} r_i \cdot P(X = r_i) + b \sum_{i \in \mathbb{N}} P(X = r_i) \\ &= a \cdot E(X) + b. \end{aligned}$$

See Exercise 77 for an explanation of the last step.

### Proposition 4.16

Let  $X$  be a random variable, and let  $a$  and  $b$  be real numbers. Then the expected value of the random variable  $aX + b$ , which is formed by composing  $X$  with the function

$$\begin{aligned}\mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto ax + b.\end{aligned}$$

has an expected value given by

$$E(aX + b) = aE(X) + b.$$

**Proof.** An argument for the discrete case is given above. The general argument proceeds as follows.

$$\begin{aligned}E(aX + b) &= \int_{-\infty}^{\infty} ax + b \cdot p(ax + b) dx \\ &= a \int_{-\infty}^{\infty} x \cdot p(x) dx + b \int_{-\infty}^{\infty} p(x) dx \\ &= aE(X) + b.\end{aligned}$$

If we have two random variables then we can say something about combining them.

### Proposition 4.17

If  $X$  and  $Y$  are random variables then

$$E(X + Y) = EX + EY.$$

If  $X$  and  $Y$  are independent then we also have

$$E(X \cdot Y) = EX \cdot EY.$$

**Exercise 89.** For the situation where a ‘best out of five’ series is played carry out the following tasks.

- Calculate the expected value for the number of matches that occur in a ‘best out of five’ series, see Exercise 52.
- Calculate the number of matches  $A$  can expect to win, see 82.
- There is a connection between these two expected values. What is it, and can you explain why it has to be like that?

We are now able to paraphrase an important law that, for example, explains why Bayesian updating works.

### Fact 11: The Law of Large Numbers

Let  $X_i$ , for  $i \in \mathbb{N}$ , be pairwise independent random variables with the same distribution. Further assume that the expected value of the  $X_i$  is  $v \in \mathbb{R}$ , and that the random variables have a finite variance (see Definition 38). Then

$$\frac{X_1 + X_2 + \cdots + X_n}{n}$$

converges towards  $v$  with probability 1, as  $n$  tends towards infinity.

**Example 4.87.** Assume we are tossing a coin, and we use the random variable  $X_n$  (say 0 for heads and 1 for tails) to express the  $n$ th coin toss. The expected value of each of the random variables is  $1/2$ . Then if we keep tossing the coin we find that with probability 1 the average

$$\frac{X_1 + X_2 + \cdots + X_n}{n}$$

will move closer and closer to  $1/2$ —in other words, the more often we toss the coin, the closer to 1 will be the ratio of heads to tails observed.

A rather simplified way of paraphrasing this law is to say that the more often we carry out a random process the closer the average of all our observations is to the expected value.

#### 4.4.7 Variance and standard deviation

The expected value of a random variable allows us to ‘concentrate’ its behaviour into just one number. But as Examples 4.76 and 4.79 illustrate, the expected value can be misleading regarding which values are likely to occur. One way of measuring how far a random variable deviates from its expected value is to do the following:

Let  $X$  be a random variable.

- Calculate the

expected value       $e$       of  $X$ .

- Create a new random variable in two steps:

- Subtract the expected value  $v$  from  $X$  to form the random variable

$$X - v.$$

- To ensure that positive and negative differences from the expected value cannot cancel each other out (and to amplify differences), form the square of the previous random variable to give

$$(X - v)^2.$$

- Calculate the expected value of the new random variable.

**Example 4.88.** We return to Example 4.67 of tossing a coin three times, where we count the number of heads seen to get a random variable  $X$ . We recall from Example 4.76 that the expected value of  $X$  is 1.5.

If we form  $X - 1.5$  we get a new random variable with range

$$\{-1.5, -.5, .5, 1.5\}$$

and pmf

-1.5	-.5	.5	1.5
1/8	3/8	3/8	1/8.

If we square the result we have the random variable  $(X - 1.5)^2$  with range

$$\{.25, 2.25\}$$

and pmf

.25	2.25
2/8 = 1/4	6/8 = 3/4.

Its expected value is

$$.25 \cdot \frac{1}{4} + 2.25 \cdot \frac{3}{4} = \frac{0.25 + 6.75}{4} = \frac{7}{4} = 1.75.$$

Hence the variance (see definition below) of the random variable  $X$  is 1.175.

### Definition 38: variance

If  $X$  be a random variable with expected value  $v$  its **variance** is given by

$$E((X - v)^2).$$

As pointed out above, the variance amplifies larger deviations from the expected value by squaring the difference, and it returns the square of the expected difference. For some considerations it is preferred not to carry the last step, leading to a slightly different way of measuring how far a random variable strays from its expected value.

### Definition 39: standard deviation

If  $X$  is a random variable then its **standard deviation** is given by the square root of its variance.

The standard deviation gives an idea of what is ‘normal’ for a given distribution. If we only consider ‘normal’ those values which are equal to the expected value then this is too narrow for most purposes. If the average height in a given population is 167cm, then we don’t consider somebody who measures 168cm far from the norm.

Typically values which are within one standard deviation on either side of the ave considered ‘normal’. If the standard deviation is large that means that there are a lot of data points away from the expected value, and we should not have too narrow an idea of what is ‘normal’.

**Example 4.89.** In the Example 4.88 the standard deviation is  $\sqrt{1.75} \approx 1.32$ . This means that for the coin example, almost anything is normal. If we increase the number of coin tosses that changes.

## 4.5 Averages for algorithms

A very important application of expected values in computer science is that of the *average complexity* of an algorithm. You will meet this idea in COMP11212 and COMP26120 (and COMP36111). Mathematically it is quite tricky to make precise the average that is formed here. In subsequent course units you will not see formal derivations of the average complexity of an algorithm, and the examples we study below give you an idea why that would take up a great deal of time. The examples we do look at stand serve as case studies that illustrate the procedure.

### 4.5.1 Linear search

Assume you have an array of integers (for example of student id numbers, pointing to the student file). Assume you are trying to find a particular id number in that array.

A simple minded algorithm for doing this will look at all the possible values in the array until the given number is found.

**Code Example 4.1.** Here's a code snippet that implements this search idea.

```
for (int index=1; index < max_index; index++)
    if (array[index]==given_number) ...
```

This algorithm is known as *linear search*. How many times is the algorithm going to perform look-up for the array on average? In other words, how often will `array[index]` be invoked? We begin by looking at an example.

**Example 4.90.** If the array has 8 entries then the chance that the entry we are looking for is any one of them is  $1/8$ . If we are lucky, and we find the entry on the first attempt<sup>31</sup> at `array[1]` then we have needed one look-up, whereas if we have to keep checking until we reach `array[8]` we need 8 look-ups. We have a random variable which takes its values in

$$\{1, 2, 3, 4, 5, 6, 7, 8\},$$

and each of these values occurs with the same probability, namely  $1/8$ .

Hence the expected value for this random variable is

$$\begin{aligned}
1 \cdot \frac{1}{8} + 2 \cdot \frac{1}{8} + \cdots + 8 \cdot \frac{1}{8} &= \sum_{i=1}^8 i \cdot \frac{1}{8} \\
&= \frac{1}{8} \sum_{i=1}^8 i \\
&= \frac{1}{8} \cdot \frac{8(8+1)}{2} \\
&= \frac{8+1}{2}.
\end{aligned}$$

This means we have to expect 4.5 look-ups on average.

Of course most real-world applications have considerably larger arrays. For this reason it pays to think about the general case.

**Example 4.91.** We now assume that we have an array with  $n$  entries, and we are applying the same search algorithm as in the previous example. The chance that our looked-for number is any one of them is

$$\frac{1}{n}.$$

If the looked-for entry is the first entry of the array then we need one look-up operation, if it is the second entry we need two look-ups, and so on until the end of the array. So we have a random variable that can take values in the set

$$\{1, 2, \dots, n\},$$

and for which the probability that any one of them occurs is  $1/n$ . Hence the expected value for this random variable is

$$\begin{aligned}
1 \cdot \frac{1}{n} + 2 \cdot \frac{1}{n} + \cdots + n \cdot \frac{1}{n} &= \sum_{i=1}^n i \cdot \frac{1}{n} \\
&= \frac{1}{n} \sum_{i=1}^n i \\
&= \frac{1}{n} \frac{n(n+1)}{2} \\
&= \frac{n+1}{2}.
\end{aligned}$$

In other words we have to look through roughly half the array on average before finding the looked-for entry. You might have been able to work this out without any knowledge of random variables, but we can now put these ideas on a firm mathematical footing.

People who study algorithms are also interested in the *worst case* which in this example is that we have to perform  $n$  look-up operations until we finally find our number.

So the average case of the algorithm is that the number of look-ups required is roughly have the size of the input, whereas the worst case is that it is the size of the input.

---

<sup>31</sup>Typically arrays start at index 0 but for our example it makes life less complicated if we start at index 1.

### 4.5.2 Binary search

In the above example we were using an algorithm that is not particularly clever. If the entries appear in the array sorted by their size then we can do much better.

Assume we are trying to solve the same problem as in the previous example, but this time we have an array whose entries are sorted. In that case we can come up with a faster algorithm effectively by making use of this extra information.

Here's the idea:<sup>32</sup> The first index we try is the one halfway through the array, say the 4th entry. If the entry at that position is the one we were looking for then we are done. If not, then if the entry at that position is below the one we are looking for then we know that the looked-for entry has to be to the right of the current position at a higher index, else to the left at a lower index. Of course we might be really lucky and have found our entry already!

We now apply the same trick again: We find an entry roughly halfway through the appropriate half of the array. If the entry at the current position is below the one we are looking for....

What's the expected number of look-ups required for this algorithm? What we do on each step is to look up one entry, and split the remaining array in two parts whose sizes differ by at most 1. We look at a concrete example to better understand the situation.

**Example 4.92.** Again we assume that we have an array of size 8. Say our array looks as follows:

1	2	3	4	5	6	7	8
1	3	4	7	15	16	17	23

If we look for the entry 17 we perform the following steps:

- We look at the entry at index 4, where we find the entry 7. This is smaller than the entry we are looking for.

1	2	3	4	5	6	7	8
1	3	4	7	15	16	17	23

We know that if our number is in the array it has to be to the right of the index 4.

- On the next step we look halfway through the indices 5, 6, 7 and 8. There are 4 entries, so (roughly) halfway along is at index 6. We find the entry 16, which is again smaller than the one we are looking for.

						17		
1	2	3	4	5	6	7	8	
1	3	4	7	15	16	17	23	

- We now have to look halfway along the indices 7 and 8. There are two entries, so halfway along is at index 7. We have found the number we were looking for,

						17		
1	2	3	4	5	6	7	8	
1	3	4	7	15	16	17	23	

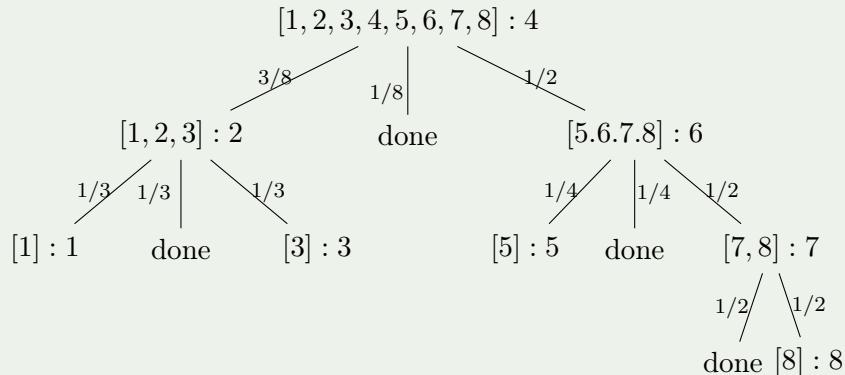

Here is a description of the algorithm when looking for an arbitrary number in this array:

We assume that we cannot be sure that the entry is in the array at all (somebody might have given us an invalid id number). On the first step we look up the entry at index 4. If this doesn't give us the entry we were looking for then this leaves us with

- either our entry is smaller than the one at index 4, so if it is there it must be at indices 1, 2 or 3, in which case
  - we look up the entry at index 2, and if we are not successful then
    - \* if our entry is below that at index 2 we look up index 1 or
    - \* if our entry is above that at index 2 we look up index 3,
  - or
- our entry is greater than the one at index 4, so if it is there at all it must be at indices 5, 6, 7 or 8, in which case we
  - look up the entry at index 6, and if that is not the correct one then
    - \* if our entry is smaller than that at index 6 we look at index 5
    - \* if our entry is greater than that at index 6 we look at index 7.
    - and if it is not at index 7 we look at index 8,

This information is more usefully collected in a tree. Here the nodes are given labels where

- the first part is a list of indices we still have to look at, then there is a colon and
- the second part is the index we are currently looking at.

We can see that in the worst case we have to look at indices 4, 6, 7 and 8, which makes four look-ups.

We can also calculate the expected value for this situation:

- The probability that we need only one look-up is  $1/8$ ;
- we need two look-ups with probability

$$3/8 \cdot 1/3 + 1/2 \cdot 1/4 = 2/8;$$

- we need three look-ups with probability

$$3/8 \cdot (1/3 + 1/3) + 1/2 \cdot (1/4 + 1/2 \cdot 1/2) = 4/8;$$

- we need four look-ups with probability  $1/2 \cdot 1/2 \cdot 1/2 = 1/8$ .

Hence the expected value for the number of look-ups is

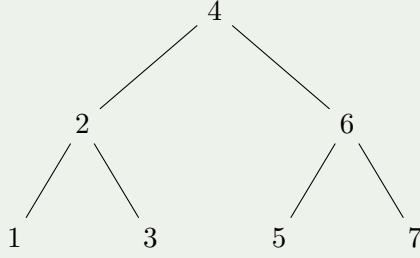

$$1 \cdot \frac{1}{8} + 2 \cdot \frac{2}{8} + 3 \cdot \frac{4}{8} + 4 \cdot \frac{1}{8} = \frac{21}{8} = 2.625.$$

Again we want to analyse the general case of this algorithm, which is known as *binary search*.

**Example 4.93.** From the example above we can see that some cases are easier to analyse than others: If we have indices that exactly fit into a tree then the calculation becomes much easier.

If we look at the example of eight indices we can see that 7 indices would fit exactly into a tree with three levels of nodes. We can also see that we don't need to have separate nodes labelled 'done'; instead, we can just use the parent node to record that the search is over. In the case where there are seven entries in the array we could calculate the expected value using the following tree, where now we only list the index that is currently looked up for each node:

<sup>32</sup>I think you will have seen this if you have been at one of our Visit Days.

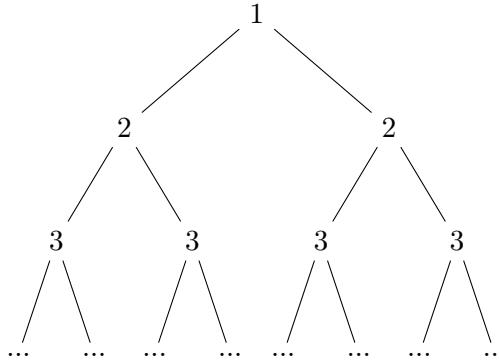

The node on the top level requires one look-up, the two nodes on the second level require two look-ups, and the four nodes on the third level require three look-ups. Each of those nodes will be equally likely to hold our number. Hence we can see that the average number of look-ups is

$$1 \cdot 1 \cdot \frac{1}{7} + 2 \cdot 2 \cdot \frac{1}{7} + 3 \cdot 4 \cdot \frac{1}{7} = \frac{17}{7} \approx 2.43.$$

We can generalize the idea from the preceding example provided that the number of indices is of the form

$$2^0 + 2^1 + \cdots + 2^{k-1} = \sum_{i=0}^{k-1} 2^i = 2^k.$$

We can think of the situation as being given as in the following tree, where on each level we give the number of look-ups required.

We start counting the levels from the top, starting with level 0 and ending at  $k - 1$ . Then

- level  $i$       has  $2^i$  nodes
- each needing  $i + 1$  look-ups
- each holding the right value with probability  $\frac{1}{2^k - 1}$ .

Hence the expected value of the number of look-ups is

$$\sum_{i=0}^{k-1} (i+1) \frac{2^i}{2^k - 1} = \frac{1}{2^k - 1} \sum_{i=0}^{k-1} (i+1) 2^i.$$

To check that we have derived the correct formula we can look at the case for  $k = 3$ , that is seven entries in the array, and compare the result we get from the formula with the one calculated above. The formula gives approximate 2.43 look-ups which agrees with the result previously calculated.

We give a few (approximate) values of this sum:

$k$	3	4	5	6	7	8
$n$	7	15	31	63	127	255
exp no look-ups	2.43	3.27	4.16	5.1	6.06	7.03

As  $k$  grows large the sum given above approximates  $k$ , If we only have values for arrays of sizes of the form

$$2^k - 1,$$

do we have to worry about the other cases? The answer is that one can show with a more complicated analysis that for an array with  $n$  entries, we require approximately  $\log n$  look-ups, even if  $n$  is not of the shape  $s^k - 1$ . This means that the average number of look-ups for an array with  $n$  entries is approximately  $\log n$ .

We note that the worst case for this algorithm is that we have to look up one node on each level in the tree, which means that in the worst case the number of look-ups is the height of the tree, which is  $\log n$ . So here we are in a situation where the average case is the same as the worst case!

Occasionally it is easier to analyse particular problem sizes, and as long as the values for other values deviate in only a minor way from the function so deduced, this is sufficient for most purposes in computer science. You will learn in COMP11212 that we are typically only interested in the ‘rate of growth’ of a function describing the number of instructions required for a given problem size, and that all other aspects of the function in question are dropped from consideration.

Often when looking at issues of complexity it is sufficient to have approximate counts, and more generally we only care about how quickly the number of instructions grows as  $n$  grows large. We look a little into how one can measure the ‘growth’ of a function in Section 5.1.

You can see from the examples given, however, that a proper analysis can be quite tricky (the cases discussed above are relatively simple ones), and that one often has to make decisions about using approximations. When people claim that an algorithm has, say *an average case quadratic complexity* then this has to be read as an approximate description of its behaviour as the input grows large. The above preceding four examples give you an idea of what is meant by ‘average number of steps’. Note that the typical assumption is that every possible configuration is equally likely (that is in our example that the sought-for number is equally likely to occur at any given index in the array), and that these assumptions are not always justified.

## 4.6 Some selected well-studied distributions

In many situations it is hard to determine the probability distribution of a given random variable from the given data. In those cases it is standard to make the assumption that it behaves according to some well known distribution.

Clearly if this assumption is not justified then any calculations based on it are not going to be of much practical use. When you are asked to cope in such a situation you should, at the very least, think about what you know about the given situation and which well-known distribution this suits best.

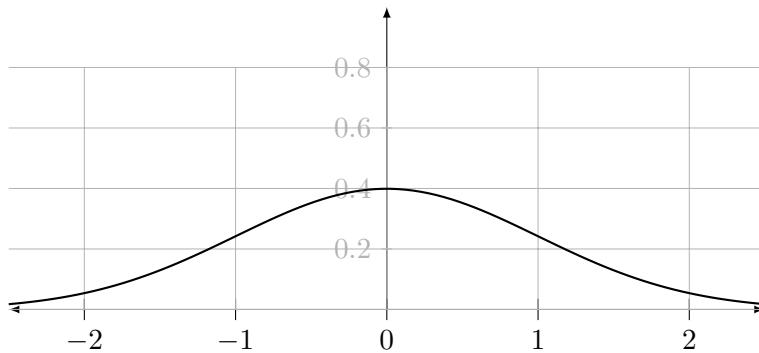

We here give an overview of only a very small number of distributions. There is plenty of material available on this topic, and so there is no need to add to that.

#### 4.6.1 Normal distributions

Normal distributions are used on many occasions. They are continuous probability distributions— although ‘normal distribution’ refers to a whole family people often use this term in the singular.

In its simplest form the probability density function of a normal distribution is given by

$$\begin{aligned} \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto \frac{1}{\sqrt{2\pi}} e^{-x^2/2}. \end{aligned}$$

The expected value of a random variable with this probability density function is 1, and the standard deviation is also 1.

It is possible to create a normal distribution for a given expected value and a given standard deviation. Let  $v$  and  $s$  be real numbers, where  $s > 0$ . Then a random variable with probability density function

$$\begin{aligned} \mathbb{R} &\longrightarrow \mathbb{R} \\ x &\longmapsto \frac{1}{s\sqrt{2\pi}} e^{-(x-v)^2/2s^2} \end{aligned}$$

has expected value  $v$  and standard deviation  $s$ .

One of the reasons that this is such a useful distribution is that, under fairly general assumptions, it is the case that the average of a (large) number of random variables which are independent and have independent distributions converges against having a normal distribution. For this reason random variables that are created from a number of independent processes obey a distribution which is close to a normal distribution.

Normal distributions are known to occur in the natural world, for example as the velocities of molecules in an ideal gas. There are many resources available to study phenomena which follow these distributions.

The normal distribution appears in the robot problem in COMP14112 to describe the accuracy of the sensor.

### 4.6.2 Bernoulli and binomial distributions

We have used Bernoulli distributions already without naming them. Given a random variable with two possible outcomes, say

$$r \quad \text{and} \quad r' \quad \text{in } \mathbb{R},$$

to give a probability distribution of the random variable it is sufficient to determine

$$P(X = r),$$

and all other probabilities are then uniquely determined (compare Corollary 4.13). In particular we know that

$$P(X = r') = 1 - P(X = r),$$

since the probability of all possible outcomes have to add up to 1.

Typically for a Bernoulli distribution we assume the only possible values of the random variable are

$$0 \quad \text{and} \quad 1.$$

**Example 4.94.** Tossing a coin is an experiment that follows a Bernoulli distribution, where one of head or tails is assigned the value 1, and the other the value 0. You can think of this as the random variable that counts the number of heads (or tails) that appear in a single coin toss.

To make the notation less tedious, assume that

$$P(X = 1) = p.$$

The expected value of this distribution is given by

$$0 \cdot (1 - p) + 1 \cdot p = p,$$

and the variance is

$$\begin{aligned} E((X - p)^2) &= E(X^2 - 2pX + p^2) \\ &= (0^2 - 2p \cdot 0 + p^2)(1 - p) + (1^2 - 2p \cdot 1 + p^2)p \\ &= p^2(1 - p) + (1 - 2p + p^2)p \\ &= p^2 - p^3 + p - 2p^2 + p^3 \\ &= p - p^2 \\ &= p(1 - p). \end{aligned}$$

The binomial distributions arise from assuming an experiment with a Bernoulli distribution is carried out repeatedly, in a way where the previous incarnations have no influence on the following ones, such as tossing a coin a number of times, and adding up the results (for example the number of heads that appear). You can find the description of the pmf, expected value, and standard deviation for these distributions from many sources, including online.

### 4.6.3 The Poisson distribution

The Poisson distribution is a discrete distribution that applies to process of a particular kind, namely ones where

- we look at the probability of how many instances of a given event occur within a given time interval or a given space,
- we know the average rate for these events and
- the events occur independently from the time of the last event.

Typical examples are:the following.

- The number of births per hour on a given day.
- The number of mutations in a set region of a chromosome.
- The number of particles emitted by a radioactive source within a given time span.
- The number of sightings of pods of dolphins along a given path followed by an observing plane.
- Failures of machines or components in a given time period.
- The number of calls to a helpline in a given time period.

It is assumed that the expected number of occurrences (on average) of the event is known, so assume we have  $v \in \mathbb{R}^+$ . A random variable  $X$  obeying the Poisson distribution has the pmf

$$P(X = n) = \frac{v^n e^{-n}}{n!}.$$

Its expected value is  $v$ , which is also the variance.

**Example 4.95.** Assume we have motherboards for which it is known that on average, .5% are faulty. If we pick a sample of 200 motherboards, what is the probability that three of them are faulty?

From the given data we would expect  $.005 \times 200 = 1$  to have one faulty board on average in such a sample, but this does not tell us how to answer the question about the probability that we have three of them. If we assume that this event follows the Poisson distribution then we get

$$P(X = 3) = \frac{1^3 e^{-3}}{3!} \approx .14,$$

so the probability is 14%.

### 4.6.4 Additional exercises

We look at situations here for which I don't want you to make any assumptions about which part of the notes you should use to solve them.

**Exercise 90.** A lecturer believes that students have a better chance of doing well on their unit if they also take another unit at the same time. He looks at the numbers from the past academic year to see whether he can find statistical evidence for his belief. In the past year he had 200 students on his course of which 40 got a very good mark. Of the student on his course 67 were enrolled on the other unit in question, and of these 27 receive a very good mark.

Do you think he is right in his belief?

**EExercise 91.** Assume you have an array whose entries are natural numbers, and you are given a natural number  $k$  that occurs in the array. You want to change the order of the entries in the array in such a way that it satisfies the following two conditions:

- All numbers which are less than  $k$  occur to the left of  $k$  and
- all numbers which are larger than  $k$  occur to the right of  $k$ .

This is a part of an important sorting algorithm called *Quicksort*. In what follows we make the assumption that the number  $k$  occurs in the array exactly once.<sup>33</sup> The way this algorithm is implemented is as follows:

- There are two pointers, low and high.
- At the start the low pointer points to the lowest index and the highest pointer points to the highest index.
- You start a loop. This loop runs until the low pointer and the high pointer point at the same entry.
  - Look at the entry the low pointer points to.
    - \* If the entry is less than  $k$  then increase the low pointer by one, check that it has not reached the index of the high pointer, and repeat.
    - \* If the entry is greater than or equal to  $k$  then do the following.
      - Look at the entry the high pointer points to.
      - If the entry is greater than  $k$  then decrease the high pointer by one, check that it has not reached the low pointer, and repeat.
      - If the entry is less than or equal to  $k$  then swap the two entries.
    - Repeat, looking again at the low pointer.

- (a) Carry out this algorithm for the following array and  $k = 17$ .

1	2	3	4	5	6	7	8
19	2	17	5	1	27	0	31

How many times does the algorithm ask you to swap elements?

Now look at carrying out the algorithm for an arbitrary array of size  $n$ .

- (b) In the best case, how many times does the algorithm have to swap elements? Justify your answer.
- (c) Assume you have an array with five elements. In the worst case, how many times does the algorithm have to swap elements? Try to generalize your idea to an array with  $n$  elements. Justify your answer by describing how to construct an array where the worst case will occur.
- (d) Assume that the element  $k$  occurs in the middle of the array and that the array has an odd number of entries. What is the average number of swaps the algorithm has to perform if you may assume that given an arbitrary element of the array,
- the probability that it is less than  $k$  is  $1/2$  and
  - the probability that it is greater than  $k$  is  $1/2$ ?

Write one sentence about how this changes if the probability that an arbitrary element of the array is less than  $k$  is  $p$ , and the probability that it is greater than  $k$  is  $1 - p$ .

- (e) On average, how many times does the algorithm have to swap elements if you may assume everything from the previous part, with the exception that the element  $k$  is located in the middle of the array?
- (f) Can you say how many times the algorithm has to swap elements on average if you are not allowed to make this assumption, but if the element  $k$  still occurs in the middle of the array?

**Exercise 92.** Assume you have a line with 11 points points from  $-5$  to  $5$ . There is an ant at point  $0$ .

Assume that with probability  $1/2$  the ant moves one point to the left, and with probability of  $1/2$  it moves one step to the right. If it wants to make a step that causes it to leave the grid it stops. *This exercise requires a lot of calculations and is a bit fiddly in places.*

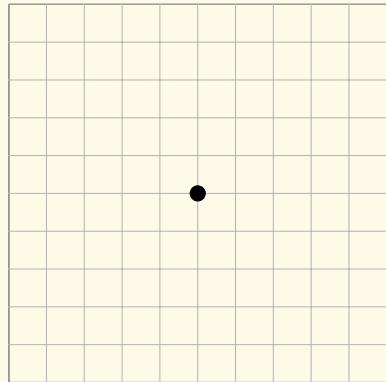

- (a) What is the probability that the ant will have stopped after 10 steps?
- (b) What is the expected position of the ant after 10 steps?

**Exercise 93.** This exercise is a generalization to 2 dimensions of the previous one, so you may want to solve that first.

Assume you have an eleven-by-eleven grid, given by the points from  $(-5, -5)$  to  $(5, 5)$  as in the following picture. There is an ant on the

<sup>33</sup>Although it also works if the number doesn't occur at all in that you get a block of numbers less than  $k$  followed by a block of numbers greater than  $k$ .

grid, initially in position  $(0, 0)$ .

Assume that with the probability of  $1/4$  the ant selects a direction from  $\{N, E, S, W\}$  and takes one step in that direction. If it wants to move in a direction that would cause it to leave the grid it stops.

- (a) What is the probability that the ant has stopped after ten steps?
- (b) What is the expected position of the ant after ten steps?

Assume that the ant is not allowed to change direction by more than  $90$  degree on each step, and that each of the possible three directions is equally likely.

- (c) What is the average distance that the ant will have from the starting point after five steps?
- (d) What is the probability that the ant will have stopped after eight steps?

**Exercise 94.** Assume you are looking after a cluster containing  $50$  machines. One of your machine has been affected by an odd virus. Its behaviour is as follows:

- It randomly picks one of the other  $49$  machines in the cluster. It copies itself to that machine. It then becomes inert.
  - If a machine that was infected previously becomes infected again it behaves as if it hadn't been infected before, that is, the virus is copied to one machine randomly picked from the other  $49$  machines in the cluster.
- (a) What is the probability that after eight infection steps, the number of infected computers is  $8$ ? (In other words, no computer has been infected twice.)
  - (b) What is the expected number of infected computers after  $5$  infection steps? *Hint: draw a tree where each node is labelled by the number of machines currently infected. On the first step there is one such machine,*

on the second step there are two (you may want to think about why), and after the third step there can be two or three.

- (c) Picture the tree that would fully describe the possible numbers of infected machines after 50 steps. How many paths in that tree lead to exactly three machines being infected? What is the probability for each of those paths?

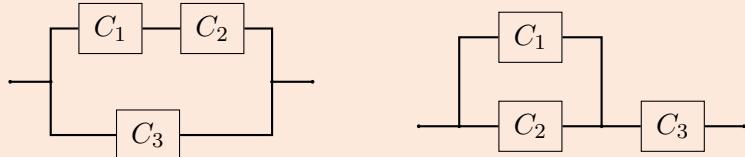

**Exercise 95.** Assume you are putting together systems using various components, and you want to work out what the chance is that a given system fails. We make the assumption that component failures are independent (not safe if we have to worry about power surges!).

You have two different ways of putting systems together, in series, or in parallel. This is indicated in a diagram as follows.

The left hand way of putting components together function provided that both of  $C_1$  and  $C_2$  function. The right hand way of connecting them will function provided that at least one of  $C_1$  and  $C_2$  functions.

Here are two further systems.

(a) Assume that component  $C_i$  fails with probability  $p_i$ . What is the probability of the four given systems failing?

(b) Assume that there is a random variable  $X_i$  for each component  $C_i$  given by the time until  $C_i$  fails. Express the expected value of the time when each system fails, based on the expected values of the  $X_i$ .

## Chapter 5

# Comparing sets and functions

In computer science we are interested in comparing functions to each other because when we decide which algorithm to choose we want to pick the one that shows the better behaviour for the given range of inputs. By ‘better behaviour’ we mean an algorithm that performs faster for the given inputs. As you will see in COMP11212 when we do this we only compare such functions regarding how fast they grow, and one of the aims of this section is to introduce that idea.

We also have to be able to compare sets with each other. In Chapter 4 there is frequently a distinction between three cases regarding random processes into

- those with a finite number of outcomes and
- those with a countable<sup>1</sup> number of outcomes and
- those we consider continuous.

This chapter makes these ideas formal. There are other applications for these ideas, and we sketch one here:

- There are countably many Java programs.
- There are uncountably many functions from  $\mathbb{N}$  to  $\mathbb{N}$ .

This mismatch tells us that there are some functions from the natural numbers to the natural numbers which cannot be implemented by a Java program.

### 5.1 Comparing functions

In Section 4.4.6 we discuss how to calculate the number of instructions that a program has to carry out on average. It is a first step to analysing the efficiency of an algorithm.

Sometimes we have a choice of programs (or algorithms) to solve a particular problem. For small problem sizes it won’t matter too much which one

---

<sup>1</sup>These are the ones where the set  $S$  of outcomes may be described in the form  $S = \{s_i \mid i \in \mathbb{N}\}$ .

we pick, but as the size of our problem grows (for example, sorting millions of entries in some array as opposed to a few tens) we need to seriously think about what is the best choice. It might be the case that some programs take so long (or requires so many resources in the form of memory) that one cannot feasibly use them.

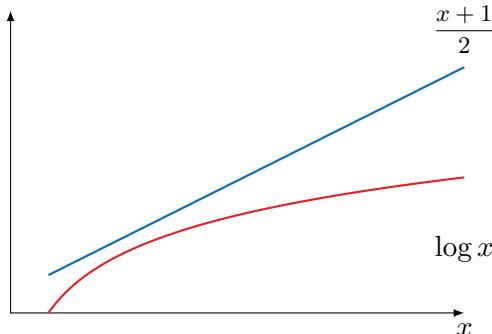

To measure the efficiency of programs it is standard to count the number of some instructions that measures how long the program is taking, depending on the size of the problem. The question then is how to compare such functions. Examples 4.91 and 4.93 in Chapter 4 give a measure of efficiency of two algorithms, the first one being known as *linear search* while the second is called *binary search*. For these algorithms we counted the number of look-up operations performed to measure their complexity.

For an array with  $n$  entries, the former has an average number of  $(n+1)/2$  look-ups to perform, while the latter requires approximately  $\log n$  look-ups.

We picture the corresponding functions by drawing their graph when viewing them as functions from  $\mathbb{R}^+$  (or a subset thereof) to  $\mathbb{R}^+$ .

instead of functions from  $\mathbb{N}$  to  $\mathbb{N}$ . In the following graph consider the two functions given

$$[1, \infty) \rightarrow \mathbb{R}^+.$$

We can see that for every input value binary search requires fewer look-ups than linear search. In this case it looks like an easy choice to make between the two. However, we have to bear in mind that binary search requires the given array to be sorted, and that does require additional computation time and power.

The picture suggests a definition for comparing functions.

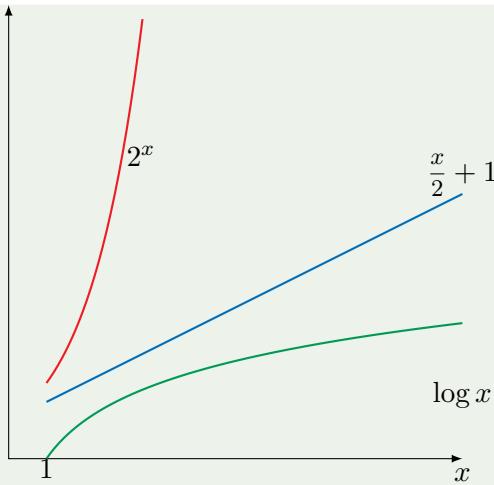

#### Definition 40: dominate

Let  $N$  be a set of numbers,  $\mathbb{N}, \mathbb{Z}, \mathbb{Q}$  or  $\mathbb{R}$ , and let  $f$  and  $g$  be two functions from a set  $S$  to  $N$ . We say that  $f$  **dominates**  $g$  (or  $f$  is above  $g$ ) if and only if

$$\text{for all } s \in S \text{ it is the case that } fs \geq gs.$$

When we draw the graphs of two functions where one dominates the other we can see that the graph of the first is entirely above the graph of the second (but the graphs are allowed to touch).

**Example 5.1.** Consider the following three functions from  $[1, \infty)$  to  $\mathbb{R}^+$ .

The function

$$x \longmapsto 2^x$$

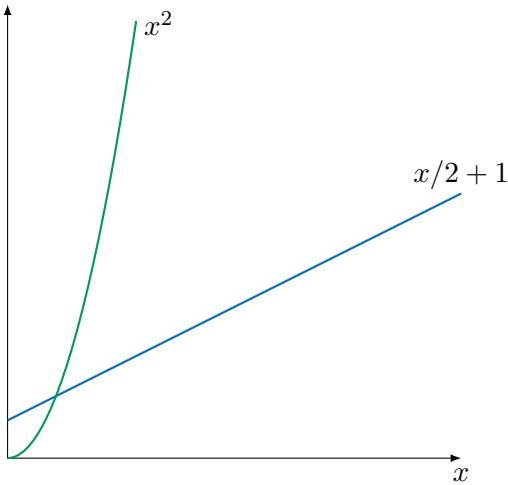

dominates the function

$$x \longmapsto x/2 + 1$$

which in turn dominates the function

$$x \longmapsto \log x .$$

But this notion is not sufficient for the intended application. If we want to establish whether one program outperforms another then using this idea for, say, the functions giving the number of instructions as a function of the size of the input for each program, may not give a useful result. Consider the functions below, going from  $\mathbb{R}^+$  to  $\mathbb{R}^+$ .

Neither function dominates the other. But clearly if the problem size is large (that is, we move to the right in the graph) then the function

$$x \longmapsto x/2 + 1$$

offers a much preferable solution. This idea is encapsulated by the following definition.<sup>2</sup>

**Definition 41: eventually dominate**

Let  $N$  and  $N'$  be sets of numbers from  $\mathbb{N}$ ,  $\mathbb{Z}$ ,  $\mathbb{Q}$  or  $\mathbb{R}$ , and let  $f$  and  $g$  be two functions from  $N$  to  $N'$ . We say that  $f$  **eventually dominates**  $g$  if and only if

there exists  $k \in \mathbb{N}$

such that      for all  $n \in \mathbb{N}$  with  $n \geq k$  we have  $fn \geq gn$ .

We can think of this as saying that  $f$  dominates  $g$  if we restrict the source of  $f$  to

$$\{n \in \mathbb{N} \mid n \geq k\},$$

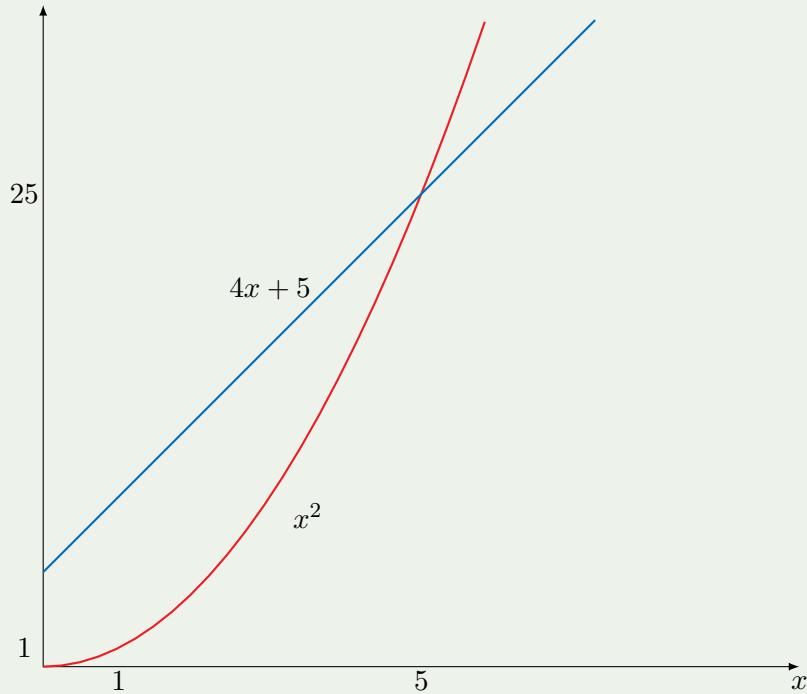

or if we only look at the graphs of the two functions to the right of  $k$ .

Note that there is no need to find the *smallest*  $k \in \mathbb{N}$  with this property—any such  $k$  will do!

**Example 5.2.** Consider the two functions

$$\begin{array}{ll} f: \mathbb{N} \longrightarrow \mathbb{N} & g: \mathbb{N} \longrightarrow \mathbb{N} \\ n \longmapsto n^2 & n \longmapsto 4n + 5. \end{array}$$

Again we use a graph to picture the situation.<sup>a</sup>

Once the two lines have crossed (at  $x = 5$ ) the graph of  $f$  stays above that of  $g$ . This suggests that we should try to find a proof that  $f$  eventually dominates  $g$ .

<sup>2</sup>You will meet the following definition again in COMP11212, and COMP21620.

- First of all, we have to give a witness for the ‘exists’ part of the statement. The graph helps us to choose  $k = 5$ , but not that every natural number larger than 5 would also work.
- Now that we have  $k$  we have to show that for all  $n \in \mathbb{N}$ , with  $n \geq k$ , we have  $gn \geq fn$ . So let us assume that  $n \in \mathbb{N}$ , and that  $n \geq 5$ . Then

$$\begin{aligned} gn &= 4n + 5 \leq 4n + n & 5 \leq n, \text{ Fact 7} \\ &= 5n \\ &\leq n \cdot n & 5 \leq n, \text{ Fact 7} \\ &= n^2 = fn \end{aligned}$$

as required.

---

<sup>a</sup>But note that drawing graphs by hand can be time-consuming, and that in order to help with answering the question whether one function is eventually dominated by another a quick imprecise sketch can be sufficient.

**Example 5.3.** Here’s an alternative way of proving the same statement.

- Again, we have to give a  $k$ , but assume this time we have not drawn the graph. We have to guess a  $k$  such that for all  $n \geq k$  we have

$$4n + 5 \leq n^2.$$

We can see that we require a number  $k$  such that multiplying with  $k$  is at least as large as multiplying with 4 and adding 5. Say we’re a bit unsure, and we are going to try to use  $k = 10$  to be on the safe side.

- We have to show that for all  $n \in \mathbb{N}$

$$\text{if } n \geq 10 \quad \text{then} \quad fn = n^2 \geq 4n + 5 = gn.$$

So assume  $n \geq 10$ . We work out that

$$\begin{aligned} gn &= 4n + 5 \leq 4n + 10 & 5 < 10, \text{ Fact 7} \\ &\leq 4n + n & 10 \leq n, \text{ Fact 7} \\ &= 5n \\ &\leq 10n & 5 < 10, \text{ Fact 7} \\ &\leq n^2 = fn & 10 \leq n, \text{ Fact 7}. \end{aligned}$$

Note that the shape of the proof has not changed much at all.

**Example 5.4.** We give another variation on this proof.

- Assume we use  $k = 10$  again, but this time we produce a proof where we start by looking at the larger function.

- Let  $n \geq 10$ . Then

$$\begin{aligned}
 fn &= n^2 = n \cdot n \\
 &\geq n \cdot 10 && n \geq 10, \text{ Fact 7} \\
 &= 4n + 6n \\
 &\geq 4n + 60 && n \geq 10, \text{ Fact 7} \\
 &\geq 4n + 5 = gn && 60 > 5, \text{ Fact 7.}
 \end{aligned}$$

**Example 5.5.** Another variant of a proof of the same statement: Instead of using the assumption  $n \geq k$  for whichever  $k$  we pick we express this as writing  $n = k + i$ , where  $i$  is an element of  $\mathbb{N}$ .

For  $k = 5$  the proof could then go like this:

$$\begin{aligned}
 gn &= g(5 + i) = 4(5 + i) + 5 && \text{def } g \\
 &= 25 + 4i && \text{calculations in } \mathbb{N} \\
 &\leq 25 + 10i && 4 \leq 10, \text{ Fact 7} \\
 &\leq 25 + 10i + i^2 && 0 \leq i^2, \text{ Fact 7} \\
 &= (5 + i)^2 && \text{calculations in } \mathbb{N} \\
 &= f(5 + i) = fn && \text{def } f.
 \end{aligned}$$

You can see from these examples that there are typically *many* ways of proving the desired statement. Different strategies are outlined in those examples, and you can pick whichever one you prefer in order to solve these kinds of questions.

**CExercise 96.** Determine whether one of the two functions given eventually dominates the other. Give a justification for your answer. You should not use advanced concepts such as limits or derivatives, just basic facts about numbers.

- $x \mapsto \log(x + 1)$  and  $x \mapsto x$  as functions from  $\mathbb{N}$  to  $\mathbb{N}$ .
- $x \mapsto x \log(x + 1)$  and  $x \mapsto x^2$  as functions from  $\mathbb{R}^+$  to  $\mathbb{R}^+$ .
- $x \mapsto 2^x$  and  $x \mapsto 1,000,000x$  as functions from  $\mathbb{Z}$  to  $\mathbb{Z}$ .
- $\sin$  and  $\cos$  as functions from  $\mathbb{R}$  to  $\mathbb{R}$ .

## 5.2 Comparing sets

In the introduction to this chapter we have argued that it is important to be able to compare the sizes of different sets. It turns out that the notions of injective and surjective functions from Section 2.5 is useful for this purpose.

In particular, if there is an injective function from a set  $S$  to a set  $T$ , then for every element of  $S$  there is an element of  $T$ , and all these elements are different. Hence we know that all elements of  $S$  ‘fit into’  $T$ , and  $T$  must be at least as big as  $S$ .

### Definition 42: comparison of set size

Let  $S$  and  $T$  be sets. We say that the **size of  $S$  is smaller than or equal to that of  $T$**  if and only if there is an injection from  $S$  to  $T$ .

**Example 5.6.** We have an injection

$$\{0, 1, 2, 3, 4\} \rightarrow \{0, 1, 2, 3, 4, 5\},$$

which is given by the assignment

$$x \longmapsto x ,$$

which is clearly an injection. So the size of the set

$$\{0, 1, 2, 3, 4\}$$

less than or equal to the size of the set

$$\{0, 1, 2, 3, 4, 5\}.$$

This may seem like a trivial observation. Our definition really only comes into its own once we consider infinite sets.

### Lemma 5.1

If  $S$  and  $T$  are sets with finitely many elements then the size of  $S$  is less than or equal to the size of  $T$  if and only if the number of elements of  $S$  is less than or equal to the number of elements of  $T$ .

**Proof.** Note that in Exercise 37 it is shown that the number of elements in the image of a set  $S$  under an injection is the same as the number of elements of  $S$ .

We show both implications separately.

- Assume that the size of  $S$  is less than or equal to the size of  $T$ . Then there is an injection, say  $f$ , from  $S$  to  $T$ . By Exercise 37 we know that the number of elements of the image  $f[S]$  of  $S$  under  $f$  is the same as the number of elements of  $S$ . Since  $f[S]$  is a subset of  $T$  we know that  $T$  has at least as many elements as  $S$ .
- Assume that the number of elements of  $S$  is less than or equal to the number of elements of  $T$ . This means that if we name the elements of  $S$ , say  $s_1, s_2, \dots, s_m$ , and those of  $T$ , say  $t_1, t_2, \dots, t_n$  then  $n \geq m$ . If we now define the function

$$\begin{aligned} \{s_1, s_2, \dots, s_m\} &\longrightarrow \{t_1, t_2, \dots, t_n\} \\ s_i &\longmapsto t_i \end{aligned}$$

from  $S$  to  $T$  it is an injection.

Here is an example with infinite sets.

**Example 5.7.** The natural numbers  $\mathbb{N}$  can be mapped via an injection into the integers  $\mathbb{Z}$  by defining

$$n \longmapsto n.$$

This is clearly an injection. Hence the size of  $\mathbb{N}$  is less than or equal to the size of  $\mathbb{Z}$ .

If I had asked in the lecture whether the size of  $\mathbb{Z}$  is at least that of  $\mathbb{N}$  I am sure everybody would have told me that this is true. You may find the following example less intuitive. It shows that once we have sets with infinitely many elements our intuitions about their sizes become suspect.

**Example 5.8.** What you might find more surprising is that  $\mathbb{Z}$  also has a size smaller than or equal to that of  $\mathbb{N}$ . We give an injection  $f: \mathbb{Z} \rightarrow \mathbb{N}$  by setting<sup>3</sup>

$$n \longmapsto \begin{cases} 2n & \text{if } n \geq 0 \\ -(2n+1) & \text{else.} \end{cases}$$

This is an injection for the following reason. Let  $m$  and  $n$  in  $\mathbb{Z}$ . We have to show that  $fm = fn$  implies  $m = n$ . Since the definition of  $f$  is by cases we have to distinguish several cases in this proof.

- $m \geq 0$  and  $n \geq 0$ . If  $2m = fm = fn = 2n$  we may conclude  $m = n$ .
- $m < 0$  and  $n < 0$ . If  $-(2m+1) = fm = fn = -(2n+1)$  we may conclude that  $2m+1 = 2n+1$  and so  $m = n$  as required.
- $m \geq 0$  and  $n < 0$ . If  $2m = fm = fn = -(2n+1)$  we get  $2m = 2n+1$  which can never hold for  $m, n$  in  $\mathbb{Z}$ .
- $m < 0$  and  $n \geq 0$ . This case is identical to the previous one where  $n$  and  $m$  have been swapped.

**Exercise 97.** Show the following statements.

- The size of every set is less than or equal to itself.
- If the size of the set  $S$  is less than or equal to the size of the set  $T$ , and if the size of the set  $T$  is less than or equal to the size of the set  $U$  then the size of  $S$  is less than or equal to the size of  $U$ .

This means that we have defined a *reflexive* and *transitive* binary relation, which means we can think of it as a kind of order. This idea is looked at in more detail in Chapter 7.4.

What does it mean that  $\mathbb{N}$  is at least as big as  $\mathbb{Z}$ , and  $\mathbb{Z}$  is at least as big as  $\mathbb{N}$ ? It means that they can be thought of as having the same size.

---

<sup>3</sup>Compare this to the function from the mid-term test in 2015/16,

### Definition 43: same set size

We say that two sets  $S$  and  $T$  **have the same size** if and only if

- the size of  $S$  is less than or equal to the size of  $T$  and
- the size of  $T$  is less than or equal to the size of  $S$ .

The previous two examples show that  $\mathbb{N}$  and  $\mathbb{Z}$  have the same size.

**CExercise 98.** Show that the following sets have the same size.

- (a)  $\mathbb{N}$  and  $\mathbb{N} \times \mathbb{N}$ ;
- (b)  $\mathbb{N}$  and  $\mathbb{N}^k$  where  $k$  is a finite number.
- (c)  $\mathbb{N}$  and  $\mathbb{Q}$ .
- (d) the set of functions from some set  $S$  to the two element set  $\{0, 1\}$  and the powerset  $\mathcal{P}S$  of  $S$ .

**Exercise 99.** Show that if there is a bijection from  $S$  to  $T$  then  $S$  and  $T$  have the same size.

You may have wondered why we used injections to determine the size of a set, and whether we could not have done this using surjections. The following exercise answers that question.

**Exercise 100.** Show that given a function  $f: S \rightarrow T$  the following are equivalent:

- (i)  $f$  is a surjection and
- (ii) the size of  $S$  is at least the size of  $T$ .

**Optional Exercise 20.** Show that if  $S$  and  $T$  have the same size then there is a bijection between them. This is known as the *Cantor-Bernstein-Schröder Theorem*.

We give a formal definition of infinity based on a notion known as *Dedekind infinite*.

### Definition 44: infinite set

A set  $S$  is **infinite** if and only if there is an injection from  $S$  to a proper subset of  $S$ .

### Proposition 5.2

A set  $S$  is infinite if and only if there is an injective function from  $S$  to itself which is not surjective.

**Proof.** We show the statement in two parts.

Assume that the set is infinite. Then there is an injective function

$$f: S \rightarrow S'$$

where  $S'$  is a proper subset of  $S$ . We can define a function

$$\begin{aligned} g: S &\longrightarrow S \\ s &\longmapsto fs \end{aligned}$$

which is obviously also injective, but it is not surjective since we know there is an element of  $S$  which is not in  $S'$ , and so cannot be in the image of  $g$ .

Assume that we have an injective function

$$g: S \rightarrow S$$

which is injective but not surjective. Then there is an element  $s$  of  $S$  which is not in the image of  $g$ , that is, there is no  $s' \in S$  with  $gs' = s$ . We define a new function

$$\begin{aligned} f: S &\longrightarrow S \setminus \{s\} \\ s &\longmapsto gs \end{aligned}$$

We note that  $f$  is injective since  $g$  is, and we note that its image is a proper subset of  $S$ .

**Example 5.9.** We show that there are infinitely many Java programs. We have to give an injective function from the set of Java programs to itself whose range does not include all Java programs.

We do this as follows: Given a Java' program we map it to the same Java program to which the line

```
System.out.println("Hello world!");
```

has been added.

This function is injective: If we have two Java programs that are mapped to the same program then they must be the same program once that new last line has been removed.

This function is not surjective since there are many programs which do not contain that line and so are not in the image of the function.

Hence this assignment from the set of all Java programs to itself is injective but not surjective, and so this set is infinite by Proposition 5.2.

**Example 5.10.** We show that the set  $\mathcal{P}_f\mathbb{N}$  of finite subsets of  $\mathbb{N}$  is infinite. We give an injective function from the  $\mathcal{PS}$  to itself and show that it is not surjective.

Given a finite non-empty subset

$$\{s_1, s_2, \dots, s_n\}$$

of  $\mathbb{N}$  we map it to the set

$$\{s_1, s_2, \dots, s_n, (s_1 + s_2 + \dots + s_n)\},$$

and we map the empty set to itself. In other words we have

$$\begin{array}{ccc} \mathcal{P}_f\mathbb{N} & \xrightarrow{\hspace{1cm}} & \mathcal{P}_f\mathbb{N} \\ \{s_1, s_2, \dots, s_n\} & \longmapsto & \begin{cases} \{s_1, s_2, \dots, s_n, (s_1 + s_2 + \dots + s_n)\} & n > 0 \\ \emptyset & \text{else.} \end{cases} \end{array}$$

This assignment maps a given non-empty set to the set where the sum of all the elements of that set has been added as an extra element. We observe that the extra element is always the largest element of the resulting set. Note that if the set we start with has only one element then it is mapped to itself by this function since no extra element is added.

This function is injective. If two sets are mapped to the same set then in particular their greatest elements must be equal, so the original sets must have had elements which add up to the same number. Moreover, all elements (if any) of the set which are below the largest element must also correspond to each other, so the sets must have been equal and our function is injective.

This function is not surjective since the set  $\{1, 2\}$  is not in the image of this function. By Proposition 5.2 we know that the given set is infinite.

We show that all infinite sets are at least as big as the set of natural numbers  $\mathbb{N}$ .

### Proposition 5.3

If  $S$  is an infinite set then there is an injection from  $\mathbb{N}$  to  $S$ .

**Proof.** Let

$$f: S \rightarrow S$$

be the function that shows that  $S$  is infinite, that is, we assume that  $f$  is injective but not surjective. Pick an element  $s$  of  $S$  which is not in the image of  $f$ .

We define a function

$$g: \mathbb{N} \rightarrow S$$

as follows: We set

$$g0 = fs, g1 = fg0 = ffs, g2 = fg1 = fffs, g3 = fg2 = fffffs, \dots$$

More generally, we set

$$gn = f^{n+1}s,$$

where the power indicates applying  $f$  the given number of times. We have to show that the resulting function is injective. If we have  $m$  and  $n$  in  $\mathbb{N}$  with

$$gm = gn,$$

then this means

$$f^{m+1}s = gm = gn = f^{n+1}s,$$

since  $f$  is injective we can conclude from this that

$$f^m s = f^n s,$$

and we can continue removing  $f$  on both sides until we have deleted all  $f$ s on one side of the equality. This means we have

$$s = f^l s$$

for some  $l \in \mathbb{N}$ . But  $s$  is not from the image of  $f$ , so we must have that  $l = 0$ , and so removing  $m$  many  $f$ s on one side is the same as removing  $n$  many  $f$ s on the other side, which means we must have  $m = n$ .

This means that the size of  $\mathbb{N}$  is less than or equal to that of every infinite set. Since  $\mathbb{N}$  itself is infinite (see Exercise 102) in this sense  $\mathbb{N}$  is the smallest infinite set.

To ensure that our notion of infinity fits well with our notion of comparing the sizes of sets we establish the following proposition.

#### Proposition 5.4

If the size of  $\mathbb{N}$  is less than or equal to the size of a set  $S$  then  $S$  is infinite.

**Proof.** Let  $f: \mathbb{N} \rightarrow S$  be the injective function which establishes that the size of  $\mathbb{N}$  is less than or equal to the size of  $S$ .

We split  $S$  into two parts as follows. Let

$$S_1 = \{s \in S \mid \text{there is } n \in \mathbb{N} \text{ such that } fn = s\}$$

and

$$S_2 = \{s \in S \mid \text{for all } n \in \mathbb{N} \text{ } fn \neq s\}.$$

Then

$$S = S_1 \cup S_2,$$

since every element is either in the range of  $f$ , and so in  $S_1$ , or it is not in the range of  $f$  and so in  $S_2$ . Note that  $S_1$  and  $S_2$  are disjoint, so every element of  $S$  is either in  $S_1$  or in  $S_2$ , but no element can be in both sets. Note that since  $f$  is injective, for every  $s$  in  $S_1$  there is a unique  $n \in \mathbb{N}$  with  $fn = s$ . Based on this we define a function  $g$  from  $S$  to itself as follows.

$$gs = \begin{cases} f(n+1) & s \in S_1, fn = s \\ s & \text{else.} \end{cases}$$

We claim that this function is injective, but not surjective. To show injectivity we have to consider four cases, similar to Example 5.8. Let  $s$  and  $s'$  be elements of  $S$ .

- $s \in S_1$  and  $n \in S_1$ . There there exist unique elements  $n$  and  $n'$  in  $\mathbb{N}$  with  $s = fn$  and  $s' = fn$  and if  $f(n+1) = gs = gs' = f(n'+1)$  then by injectivity of  $g$  we have  $n = n'$ , and so  $s = fn = fn' = s'$ .
- $s \in S_2$  and  $s' \in S_2$ . If  $s = gs = gs' = s'$  we immediately have  $s = s'$ .
- $s \in S_1$  and  $s' \in S_2$ . We know that there exists a unique  $n \in \mathbb{N}$  with  $s = fn$ . But now  $gs = f(n+1)$  is an element of  $S_1$ , while  $gs' = s'$  is an element of  $S_2$  and so the two cannot be equal.
- $s \in S_2$  and  $s' \in S_1$ . This case is identical to the previous one where  $s$  and  $s'$  have been swapped.

We can see that the function  $g$  maps the set  $S_1$  to itself, while it maps  $S_2$  to itself as well, leaving every element as it is. The function  $g$  is not surjective since no element is mapped to  $f0$ :

Clearly  $f0$  is in  $S_1$ , so by the previous observation if it were in the image of  $g$  there would have to be an element  $s \in S_1$  with  $gs = f0$ . But for any such  $s$  we know that there exists a unique  $n \in \mathbb{N}$  with  $s = fn$ , and so we would have

$$gs = f(n+1) = f0,$$

which by injectivity of  $f$  would imply  $n+1 = 0$ , but no such number  $n$  exists in  $\mathbb{N}$ .

**Exercise 101.** Show that if a set has a finite number of elements then it is not infinite.

**EExercise 102.** Show that the following sets are infinite.

- (a)  $\mathbb{N}$ ,
- (b)  $\mathbb{R}$ ,
- (c) the set of functions from  $\mathbb{N}$  to the two element set  $\{0, 1\}$  or the powerset  $\mathcal{P}\mathbb{N}$  (you choose),
- (d) every superset of an infinite set.
- (e) Any set which is the target of an injective function whose source is infinite.

**Optional Exercise 21.** Show that if a set is not infinite then it has a finite number of elements.

**Exercise 103.** Show that if  $S$  is a set with a finite number of elements then so is its powerset  $\mathcal{P}S$ . Do so by determining the number of elements of  $\mathcal{P}S$ .

In computer science we particularly care about sets whose size is at most as big as that of the natural numbers. This is because given a finite number of symbols there are only countably many strings (and so programs) that can be expressed using those symbols.

**Definition 45: countable/uncountable**

A set is **countable** if and only if there is an injection from it to the natural numbers. A set is **uncountable** if and only if there is no injection from it to the natural numbers. A set is **countably infinite** if it is both, countable and infinite.

Note that every finite set is countable.

Examples of countably infinite sets are:

- The set of natural numbers  $\mathbb{N}$ .
- The set of integers  $\mathbb{Z}$ .
- The set of rational numbers  $\mathbb{Q}$ .
- The set of finite subsets of  $\mathbb{N}$ ,  $\mathcal{P}_f\mathbb{N}$ .
- The set of all programs in your favourite programming language.
- The set of all strings over a finite alphabet.

Examples of uncountable sets are:

- The set of real numbers  $\mathbb{R}$ ,
- the set of complex numbers  $\mathbb{C}$ ,
- the set of all subsets of  $\mathbb{N}$ ,  $\mathcal{P}\mathbb{N}$ ,
- the set of all functions from  $\mathbb{N}$  to  $\mathbb{N}$ .

Note that the last example, together with the following exercise, illustrates that there are functions from  $\mathbb{N}$  to  $\mathbb{N}$  for which we cannot write a computer program!

**Optional Exercise 22.** Assume we have a finite set of symbols, say  $A$ .

- (a) Show that  $A^k$  is finite for every  $k \in \mathbb{N}$ .
- (b) Show that

$$\bigcup_{k \in \mathbb{N}} A^k$$

is countable.

- (c) Show that there is a bijection between the set of finite strings built with symbols from  $A$  and the set  $\bigcup_{k \in \mathbb{N}} A^k$ ,

- (d) Conclude that there are countably many strings over the alphabet  $A$ .
- (e) Put together a set of symbols such that every Java program can be built from those symbols.
- (f) Prove that there is an injection from the set of Java programs to the set of strings over this set of symbols.
- (g) Conclude that the set of Java programs is countable.

### Proposition 5.5

A set is countable if and only if its size is at most that of  $\mathbb{N}$ .

**Proof.** If a set  $S$  is countable then by definition of that notion there exists an injection from  $S$  to  $\mathbb{N}$ , and by the definition of the size of a set this means that  $S$  is less than or equal to that of  $\mathbb{N}$ .

Assume that  $S$  is at most as big as  $\mathbb{N}$ . Then there is an injection from  $S$  to  $\mathbb{N}$  and so  $S$  is countable.

In Chapter 4 the notion of a countable set appears. Indeed, in general, the definition of  $\sigma$ -algebra should refer to countable sets instead of talking about sets indexed by the natural numbers. In that chapter the notion is avoided as far as possible since the formal definition does not appear until a later chapter. We use this opportunity to connect the two ideas.

### Proposition 5.6

If  $S$  is countable then there is a way of listing all its elements, that is, there is a surjective function  $g$  from  $\mathbb{N}$  to  $S$ , allowing us to list all the elements of  $S$  as

$$g_0, g_1, g_2, g_3, \dots$$

and we may think of them as

$$s_0, s_1, s_2, \dots$$

where we delete any repeated elements from the list.

If  $S$  is a set such that there is a surjective function from  $\mathbb{N}$  to  $S$  then  $S$  is countable.

**Proof.** We prove the first statement. Since  $S$  is countable there is an injective function

$$f: S \rightarrow \mathbb{N}.$$

We use this function as follows: By Proposition 2.2 there is an injective function

$$g: S \rightarrow \mathbb{N}$$

with the property that

$$g \circ f = \text{id}_S.$$

This function is surjective, since given  $s \in S$  we know that

$$s = \text{id}_S s = gfs,$$

so we have found  $fs \in \mathbb{N}$  which is mapped by  $g$  to  $s$ . This completes the proof.

To prove the second statement assume we have a surjective function

$$g: \mathbb{N} \rightarrow S.$$

By Exercise 100 this means that the size of  $S$  is at most the size of  $\mathbb{N}$ , and by Proposition 5.5 we have completed the proof.

**Optional Exercise 23.** Show that every uncountable set is at least as big as any countable set.

**Exercise 104.** Show that every subset of a countable set is countable. Conclude that every superset of an uncountable set is uncountable.

**Optional Exercise 24.** Show that the following sets do not have the same size.

- (a) Any set and its powerset;
- (b)  $\mathbb{N}$  and  $\mathbb{R}$ . Conclude that  $\mathbb{R}$  is not countable.

As a consequence of Exercises 22 and 24 we can see, for example, that there are more real numbers than there are Java programs. This means that if we cannot hope to write a Java program that outputs the digits of a given real number, one at a time, for every real number.

**Optional Exercise 25.** Show that any two countably infinite sets have the same size.

# Glossary

<b><math>\sigma</math>-algebra</b>	134
The set of events of a probability space. Contains the whole set of outcomes and is closed under the complement operation and forming unions of countable collections of sets.	
<b>absolute, <math> \cdot </math></b>	18, 55
Defined for various sets of numbers, here extended to complex numbers. Given a complex number $a + ib$ we have $ a + ib  = \sqrt{a^2 + b^2}$ .	
<b>and</b>	67
Connects two properties or statements, both of which are expected to hold.	
<b>argument</b>	58
The argument of a complex number is the angle it encloses with the positive branch of the real axis.	
<b>associative</b>	84
A binary operation is associative if and only if it gives the same result when applied two three inputs, no matter whether it is first applied to the first two, or first applied to the last two of these.	
<b>Bayes's Theorem</b>	159
The equality which says that, given events $A$ and $B$ , the probability that $B$ given $A$ is the probability that $A$ given $B$ , multiplied by the probability of $B$ and divided by that of $A$ .	
<b>bijective</b>	107
A function is bijective if and only if it is both, injective and surjective. A bijective function is called a bijection.	
<b>binary operation</b>	37, 83
A function of the type $S \times S \rightarrow S$ , which takes two elements of a set $S$ as input and produces another element of $S$ .	
<b>binary relation</b>	50
A connection between a source set $S$ and a target set $T$ which is not necessarily a function. It is specified by the collection of all pairs of the form $(s, t)$ in $S \times T$ that belong to it.	

The complex numbers as a set with a number of operations.

<b>commutative</b>	87
--------------------	----

A binary operation is commutative if and only if it gives the same result when its two inputs are swapped.

<b>complement</b>	30
-------------------	----

The complement of a set  $S$  is always taken with respect to an underlying set, and it consists of those elements of the underlying set which do not belong to  $S$ .

<b>composite of functions</b>	40
-------------------------------	----

The composite of two functions is defined provided the target of the first is the source of the second. It is the function resulting from taking an element of the source of the first function, applying the first function, and then applying the second to the result.

<b>conditional probability</b>	156
--------------------------------	-----

Given two events  $A$  and  $B$ , where  $B$  has non-zero probability, the conditional probability of  $A$  given  $B$  is the probability of  $A \cap B$  divided by the probability of  $B$ .

<b>conjugate, <math>\bar{\cdot}</math></b>	61
--	----

The conjugate  $\bar{z}$  of a complex number number  $z = a + ib$  is  $a - ib$ .

<b>continuous</b>	182
-------------------	-----

A random variable is continuous if and only if it is not discrete.

<b>countable</b>	247
------------------	-----

A set is countable if and only if there is an injective function from it to  $\mathbb{N}$ .

<b>countably infinite</b>	247
---------------------------	-----

A set is countably infinite if it is both, countable and infinite.

<b>cumulative distribution function (cdf)</b>	195
---	-----

The cdf of a random variable maps each element  $r$  of  $\mathbb{R}$  to the probability that the random variable has a value less than or equal to  $r$ .

<b>definition by cases</b>	47
----------------------------	----

A way by piecing together functions to give a new function.

<b>discrete</b>	182
-----------------	-----

A random variable is discrete if and only if its range is countable.

<b>disjoint</b>	30
-----------------	----

Two sets are disjoint if they have no elements in common.

**divides** 17, 20

A number  $m$  divides a number  $n$  in some set of numbers if there exists a number  $k$  with the property that  $n = km$ .

**divisible** 17, 20

We say for natural numbers (or integers) that  $n$  is divisible by  $m$  if and only if  $n$  leaves remainder 0 when divided by  $m$  using integer division.

**dominate** 235

A function  $f$  from a set  $X$  to  $\mathbb{N}$ ,  $\mathbb{Z}$ ,  $\mathbb{Q}$  or  $\mathbb{R}$  dominates another  $g$  with the same source and target if and only if the graph of  $f$  lies entirely above the graph of  $g$  (graphs touching is allowed).

**empty set,  $\emptyset$**  27

A set which has no elements.

**even** 17, 20

An integer (or natural number) is even if and only if it is divisible by 2.

**eventually dominate** 237

A function  $f$  from  $\mathbb{N}$  to  $\mathbb{N}$  eventually dominates another  $g$  with the same source and target if and only if there is some number beyond which the graph of  $f$  lies above that of  $g$  (graphs touching is allowed). The analogous definition works for functions with source and target  $\mathbb{Z}$ ,  $\mathbb{Q}$  or  $\mathbb{R}$ .

**expected value** 206

The expected value of a random variable can be thought of as the average value it takes. It is given by the integral of the product of a number which the probability that it is the value of the random variable. If the random variable is discrete then this is given by a sum.

**for all** 73

Expresses a statement or property that holds for all the entities specified.

**function** 38

A function has a source and a target, and contains instructions to turn an element of the source set into an element of the target set. Where partial functions are discussed sometimes known as **total function**.

**graph of a function** 42

The graph of a function  $f$  with source  $S$  and target  $T$  consists of all those pairs in  $S \times T$  which are of the form  $(s, fs)$ .

**group** 94

A set with an associative binary operation which has a unit and in which every element has an inverse.

<b>identity function</b>	39
The identity function on a set is a function from that set to itself which returns its input as the output.	
<b>if and only if</b>	72
Connects two properties or statement, and it is expected that one holds precisely when the other holds.	
<b>image of a set, <math>f[\cdot]</math></b>	41
The image of a set consists of the images of all its elements, and one writes $f[S]$ for the image of the set $S$ under the function $f$ .	
<b>image of an element</b>	41
The image of an element under a function is the output of that function for the given element as the input.	
<b>imaginary part</b>	53
Every complex number $a + bi$ has an imaginary part $b$ .	
<b>implies</b>	70
Connects two properties or statements, and if the first of these holds then the second is expected to also hold.	
<b>independent</b>	152, 203
Two events are independent if and only if the probability of their intersection is the product of their probabilities. Two random variables are independent if and only if for every two events it is the case that the probability that the two variables take values in the product of those events is the product of the probabilities that each random variable takes its value in the corresponding event..	
<b>infinite</b>	242
A set is infinite if and only if there is an injection from it to a proper subset.	
<b>injective</b>	96
A function is injective if and only if the same output can only arise from having the same input. An injective function is called an injection.	
<b>integer</b>	18
A whole number that may be positive or negative.	
<b>integer division, div</b>	16, 19
The integer $n \text{ div } m$ is defined as the number of times $m$ divides $n$ (leaving a remainder).	
<b>intersection, <math>\cap</math></b>	28
The intersection of two sets $S$ and $T$ is written as $S \cap T$ , and it consists of all the elements of the underlying set that belong to both, $S$ and $T$ . The symbol $\bigcap$ is used for the intersection of a finite number of sets.	

<b>inverse</b>	92
One element is the inverse for another with respect to a binary operation if and only if when using the two elements as inputs (in either order) to the operation the output is the unit.	
<b>inverse function</b>	108
A function is the inverse of another if and only if the compose (either way round) to give an identity function.	
<b>law of total probability</b>	162
A rule that allows us to express the probability of an event from probabilities that split the event up into disjoint parts.	
<b>measurable</b>	179
A function from the sample set of a probability space to the real numbers is measurable if and only if for every interval it is the case that the set of all outcomes mapped to that interval is an event.	
<b>monoid</b>	92
A set with an associative binary operation which has a unit.	
<b>multiplication law</b>	159
The equality which says that given events $A$ and $B$ , the probability of the intersection of $A$ and $B$ is that of $A$ given $B$ multiplied with that of $B$ .	
<b><math>\mathbb{N}</math></b>	14
The natural numbers as a set with a number of operations. This set and its operations are formally defined in Section 6.4.	
<b>natural number</b>	14
One of the ‘counting numbers’, 0, 1, 2, 3,....	
<b>odd</b>	17, 20
An integer (or natural number) number is odd if it is not even or, equivalently, if it leaves a remainder of 1 when divided by 2.	
<b>or</b>	69
Connects two properties or statements, at least one of which is expected to hold.	
<b>pairwise disjoint</b>	135
A collection of sets has this property if any two of them have an empty intersection.	
<b>polynomial equation</b>	24
An equation of the form $\sum_{i=0}^n a_i x^i$ .	

<b>polynomial function</b>	45
A function from numbers to numbers whose instruction is of the form $x$ is mapped to $\sum_{i=1}^n a_i x^i$ (where the $a_i$ are from the appropriate set of numbers).	
<b>powerset, <math>\mathcal{P}</math></b>	38
The powerset of a set $S$ is the set of all subsets of $S$ .	
<b>prime</b>	81
A natural number or an integer is prime if its dividing a product implies its dividing one of the factors.	
<b>probability density function</b>	144
A function from some real interval to $\mathbb{R}^+$ with the property that its integral over the interval is 1 and whose integral over subintervals always exists.	
<b>probability distribution</b>	136
A function from the set of events that has the property that the probability of a countable family of pairwise disjoint sets is the sum of the probabilities of its elements.	
<b>probability mass function (pmf)</b>	194
The pmf of a discrete random variable maps each element of the range of that random variable to the probability that it occurs.	
<b>probability space</b>	135
A sample set together with a set of events and a probability distribution.	
<b>product of two sets</b>	36
A way of forming a new set by taking all the ordered pairs whose first element is from the first set, and whose second element is from the second set.	
<b>proper subset</b>	28
A set $S$ is a proper subset of the set $T$ if and only if $S$ is a subset of $T$ and there is at least one element of $T$ which is not in $S$ .	
<b><math>\mathbb{Q}</math></b>	21
The set of all rational numbers together with a variety of operations, formally defined in Chapter 7.	
<b><math>\mathbb{R}^+</math></b>	24
The set of all real numbers greater than or equal to 0.	
<b><math>\mathbb{R}</math></b>	24
The set of all real numbers.	

<b>random variable</b>	179
------------------------	-----

A random variable is a measurable function from the set of outcomes of some probability space to the real numbers.

<b>range of a function</b>	41
----------------------------	----

The range of a function is the set of all elements which appear as the output for at least one of the inputs, that is, it is the collection of the images of all the possible inputs.

<b>rational number</b>	21
------------------------	----

A number is rational if it can be written as the fraction of two integers. A formal definition is given on page 381 (and the preceding pages).

<b>real number</b>	23
--------------------	----

We do not give a formal definition of the real numbers in this text.

<b>real part</b>	53
------------------	----

Every complex number  $a + bi$  has a real part  $a$ .

<b>remainder for integer division, mod</b>	16
--	----

The integer  $n \text{ mod } m$  is defined to be the remainder left when dividing  $n$  by  $m$  in the integers.

<b>set difference, \</b>	30
--------------------------	----

The set difference  $S \setminus T$  consists of all those elements of  $S$  which are not in  $T$ .

<b>size of a set</b>	240, 242
----------------------	----------

A set is smaller than another if there exists an injective function from the first to the second. They have the same size if they are both smaller than the other.

<b>standard deviation</b>	219
---------------------------	-----

The standard deviation of a random variable is given by the square root of its variance.

<b>surjective</b>	101
-------------------	-----

A function is surjective if and only if every element of the target appears as the output for at least one element of the input. This means that the image of the function is the whole target set. A surjective function is called a surjection.

<b>there exists</b>	75
---------------------	----

Expresses the fact that a statement or property holds for at least one of the entities specified.

<b>union, <math>\cup</math></b>	28
---------------------------------	----

The union of two sets  $S$  and  $T$  is written as  $S \cup T$ . It consists of all elements of the underlying set that belong to at least one of  $S$  and  $T$ . The symbol  $\bigcup$  is used for the union of a finite number of sets.

<b>uncountable</b>	247
--------------------	-----

A set is uncountable if it is not countable.

<b>unique existence</b>	77
-------------------------	----

A more complicated statement requiring the existence of an entity, and the fact that this entities is unique with the properties specified.

<b>unit</b>	89
-------------	----

An element of a set is a unit for a binary operation on that set if and only if applying the operation to that, plus any of the other elements, returns that other element.

<b>variance</b>	219
-----------------	-----

The variance of a random variable with expected value  $e$  is given by the expected value of the random variable constructed by squaring the result of subtracting  $e$  from the original random variable.

<b><math>\mathbb{Z}</math></b>	18
--------------------------------	----

The integers with various operations, formally defined on page [378](#).

# COMP11120, Semester 1

## Exercise Sheet 0

For examples classes in Week 1

### Core Exercises marked this week

Exercise 7 on page 35.

Exercise 8 on page 40.

Exercise 9 on page 48.

### Extensional Exercises marked this week

Exercise 6 on page 31.

Exercise 10 on page 49.

Remember that

- the deadline is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

You should make sure this week that you understand the content and in particular the notation used in Chapter 0

# COMP11120, Semester 1

## Exercise Sheet 1

For examples classes in Week 2

### Core Exercises marked this week

**Exercise 12** on page 57.

**Exercise 16** on page 60.

**Exercise 21** on page 61. Carry out your proof in the style of that given on page 56 as far as you can.

### Extensional Exercises marked this week

**Exercise 18** on page 61. Carry out your proof in the style of that given on page 56 as far as you can.

**Exercise 19** on page 61.

Remember that

- the **deadline** is the beginning of the **examples class**, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could potentially do this week are all those in Chapter 1.

# COMP11120, Semester 1

## Exercise Sheet 2

For examples classes in Week 3

### Core Exercises marked this week

**Exercise 24** on page 83. Do three of the parts, one from (a)–(c) and two from (d)–(g).

**Exercise 25** on page 86. Do three of the parts, one from (a)–(d), one from (e)–(f) and one from (g)–(i).

**Exercise 26** on page 89. Do two of the parts, one from (a)–(d) and one from (e)–(g).

### Extensional Exercises marked this week

**Exercise 27** on page 92. Do two of the parts, one from (a)–(b) and one from (c)–(e). If you prefer you may do **Exercise 29** instead.

**Exercise 32** on page 94.

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could do this week or those in Sections 2.1 to 2.4.

# COMP11120, Semester 1

## Exercise Sheet 3

For examples classes in Week 4

### Core Exercises marked this week

**Exercise 35** on page 100. Do three of the parts, one from (a)–(c), one from (d)–(f), and one from (g)–(i). *Hint: If you find this hard then try to do the previous exercise first, where you know what the answer is in each case.*

**Exercise 39** on page 105. Do three of the parts, one from (a)–(d), one from (e)–(f), and one from (g)–(h). *Hint: If you find this hard then try to do the previous exercise first, where you know what the answer is in each case.*

**Exercise 41** on page 106. Do two of the parts, one from (a)–(c) and one from (d)–(f).

### Extensional Exercises marked this week

**Exercise 36** on page 100. Do any three parts.

**Exercise 45** on page 112.

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer **questions** by the TA, referring to your **rough work** as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for **numbers**), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those **ideas** to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your **understanding** failed.

Exercises you could do this week are those in Section 2.5.

# COMP11120, Semester 1

## Exercise Sheet 7

### For examples classes in Week 9

#### Core Exercises marked this week

Where the answers are probabilities don't just give a number, give an expression that explains how you got to that number!

**Exercise 49** on page 123. Do three of the parts, one from (a)–(d), one from (e)–(f) and one from (g)–(i).

**Exercise 50** on page 130.

**Exercise 54** on page 131.

#### Extensional Exercises marked this week

**Exercise 52** on page 131.

**Exercise 57** on page 135. *This is ahead of the lecture material but only requires calculating with sets. It covers important ideas for material to come.*

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could do this week are those in Section 4.1.

# COMP11120, Semester 1

## Exercise Sheet 8

For examples classes in Week 10

### Core Exercises marked this week

Where the answers are probabilities don't just give a number, give an expression that explains how you got to that number!

**Exercise 59** on page 143. Do one from Exercise 49 (a)–(l) and two from Exercises 54 to 56.

**Exercise 66** on page 158.

**Exercise 70** on page 163.

### Extensional Exercises marked this week

**Exercise 60** on page 146. Do any two parts.

**Exercise 64** on page 157.

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could do this week are those in Sections 4.2 to Section 4.3.3.

# COMP11120, Semester 1

## Exercise Sheet 9

For examples classes in Week 11

### Core Exercises marked this week

Where the answers are probabilities don't just give a number, give an expression that explains how you got to that number!

**Exercise 74** on page 177.

**Exercise 80** on page 193.

**Exercise 81** on page 198.

### Extensional Exercises marked this week

**Exercise 82** on page 198.

**Exercise 84** on page 205.

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could do this week are those in Section 2.5.

# COMP11120, Semester 1

## Exercise Sheet 10

For examples classes in Week 12

### Core Exercises marked this week

Where the answers are probabilities don't just give a number, give an expression that explains how you got to that number!

**Exercise 85** on page 210.

**Exercise 95** on page 234.

**Exercise 96** on page 240. Do one from (a)–(b) and one from (c)–(d).

### Extensional Exercises marked this week

**Exercise 87** on page 216.

**Exercise 91** on page 231. Carry out parts (a)–(d).

Remember that

- the **deadline** is the beginning of the examples class, and that you have to be able to promptly answer questions by the TA, referring to your rough work as needed;
- you may only use concepts which are defined in these notes (Chapter 0 establishes concepts for numbers), and for every concept you do use you should find the definition in the notes and work with that;
- you should justify each step in your proofs;
- if you are stuck on an exercise move on to the next one after ten minutes, but write down why you got stuck so that you can explain that to the TA in the examples class.
- In order for you to be considered as having seriously tried an exercise you must have written down the number of relevant examples and definitions in the notes, and you must be able to tell the TA what you tried to apply those ideas to the given problem. If you didn't understand the examples/definitions you must be able to tell them where exactly your understanding failed.

Exercises you could do this week are those in Section 2.5.
